## Analysis

Assume $\boldsymbol{G}=\left\{\boldsymbol{R}_{\mathbf{1}}, \boldsymbol{R}_{\mathbf{2}}, \ldots, \boldsymbol{R}_{\mathbf{r}}\right\}$ with start symbol $\boldsymbol{R}_{\mathbf{1}}$

- $f$ (length, start pos, variable index).
- Number of subproblems: $\boldsymbol{O}\left(r n^{2}\right)$
$-{ }^{-5 p a}$ ค $0(m$ sur $P$ is set of rules
- Total time: $\mathbf{O}\left(|\boldsymbol{P}| r n^{3}\right)$ which is polynomial in both $|w|$ and $|G|$. For fixed $G$ the run time is cubic in input string length.
- Running time can be improved to $O\left(n^{3}|P|\right)$
- Not practical for most programming languages. Most languages assume restricted forms of CFGs that enable more efficient parsing algorithms.
