Graph notation and represetation

## Notation and Convention

## Notation

An edge in an undirected graphs is an unordered pair of nodes and hence it is a set. Conventionally we use $\boldsymbol{u v}$ for $\{\boldsymbol{u}, \boldsymbol{v}\}$ when it is clear from the context that the graph is undirected.
(1) $\boldsymbol{u}$ and $\boldsymbol{v}$ are the end points of an edge $\{\boldsymbol{u}, \boldsymbol{v}\}$
(2) Multi-graphs allow
(1) loops which are edges with the same node appearing as both end points
(2) multi-edges: different edges between same pairs of nodes
(3) In this class we will assume that a graph is a simple graph unless explicitly stated otherwise.

## Graph Representation I

## Adjacency Matrix

Represent $\boldsymbol{G}=(\boldsymbol{V}, \boldsymbol{E})$ with $\boldsymbol{n}$ vertices and $\boldsymbol{m}$ edges using a $\boldsymbol{n} \times \boldsymbol{n}$ adjacency matrix $\boldsymbol{A}$ where
(1) $A[i, j]=A[j, i]=1$ if $\{i, j\} \in E$ and $A[i, j]=A[j, i]=0$ if $\{i, j\} \notin E$.
(2) Advantage: can check if $\{i, j\} \in E$ in $O(1)$ time
( Disadvantage: needs $\Omega\left(\boldsymbol{n}^{2}\right)$ space even when $\boldsymbol{m} \ll \boldsymbol{n}^{2}$

## Graph Representation II

## Adjacency Lists

Represent $G=(\boldsymbol{V}, \boldsymbol{E})$ with $\boldsymbol{n}$ vertices and $\boldsymbol{m}$ edges using adjacency lists:
(1) For each $\boldsymbol{u} \in \boldsymbol{V}, \operatorname{Adj}(\boldsymbol{u})=\{\boldsymbol{v} \mid\{u, v\} \in E\}$, that is neighbors of $\boldsymbol{u}$. Sometimes $\operatorname{Adj}(\boldsymbol{u})$ is the list of edges incident to $\boldsymbol{u}$.
(2) Advantage: space is $\boldsymbol{O}(\boldsymbol{m}+\boldsymbol{n})$
(3) Disadvantage: cannot "easily" determine in $O(1)$ time whether $\{i, j\} \in E$
(1) By sorting each list, one can achieve $\boldsymbol{O}(\log \boldsymbol{n})$ time
(2) By hashing "appropriately", one can achieve $\boldsymbol{O}(1)$ time

Note: In this class we will assume that by default, graphs are represented using plain vanilla (unsorted) adjacency lists.

## A Concrete Representation

- Assume vertices are numbered arbitrarily as $\{1,2, \ldots, n\}$.
- Edges are numbered arbitrarily as $\{1,2, \ldots, \boldsymbol{m}\}$.
- Edges stored in an array/list of size $\boldsymbol{m} . \boldsymbol{E}[j]$ is $j$ th edge with info on end points which are integers in range 1 to $n$.
- Array Adj of size $\boldsymbol{n}$ for adjacency lists. Adj[i] points to adjacency list of vertex $\boldsymbol{i}$. $\operatorname{Adj}[i]$ is a list of edge indices in range 1 to $\boldsymbol{m}$.

## A Concrete Representation

## Array of edges E

Array of adjacency lists

## A Concrete Representation: Advantages

- Edges are explicitly represented/numbered. Scanning/processing all edges easy to do.
- Representation easily supports multigraphs including self-loops.
- Explicit numbering of vertices and edges allows use of arrays: $O(1)$-time operations are easy to understand.
- Can also implement via pointer based lists for certain dynamic graph settings.
