CS/ECE 374 A ♦ Fall 2025

Due Wednesday, September 3, 2025 at 9pm Central Time

- Submit your solutions electronically on Gradescope as PDF files.
 - Submit a separate PDF file for each numbered problem.
 - Groups of up to three people can submit joint solutions. *Exactly one* student in each group should upload the solution to Gradescope and indicate their other group members.
 - You can find a Lagar solution template on the course web site, which we encourage
 you to use to typeset your homework.
 - If you plan to submit scanned handwritten solutions, please use dark ink (not pencil) on white unlined paper (not notebook or graph paper), and use a scanner or a scanning app to create a high-quality PDF for submission (not a raw photo). We reserve the right to reject submissions that are difficult to read.
 - If you plan to use a tablet and a note-taking app, please make sure your submitted PDF is broken into standard US-letter sized pages (not a long scroll).
- You may use any source at your disposal—paper, human, or electronic—but you *must* cite every source that you use, and you *must* write everything yourself in your own words. You are responsible for all errors in your submissions. In particular:
 - Every submitted solution *must* include a list of all sources and collaborators. (If you didn't consult any sources or collaborators, write "Sources and collaborators: None".)
 - If you use any large language model for any purpose, you *must* include a complete transcript of *all* prompts and responses as an appendix to your solution.
- *Standard grading rubrics* for many problem types can be found on the course web page. For example, most problems in Homework 1 will be graded using our standard induction rubric. Please familiarize yourself with these rubrics *before* you submit your solutions.
- Each homework will include at least one fully *solved problem*, similar to that week's assigned problems. These model solutions show the structure, presentation, and level of detail that we recommend in your homework solutions. (So do the lab solutions.) We strongly recommend reading them *before* submitting your homework solutions.

See the course web site for more information.

If you have any questions about these policies, please don't hesitate to ask in lecture, in labs, in office hours, or online.

- 1. Consider the set of strings $L \subseteq \{0,1\}^*$ defined recursively as follows:
 - The empty string ε is in L.
 - For any two strings x and y in L, the string 0x1y is also in L.
 - For any two strings x and y in L, the string 1x0y is also in L.
 - These are the only strings in *L*.

Let #(a, w) denote the number of times symbol a appears in string w; for example, #(0,01000110111001) = #(1,01000110111001) = 7.

- (a) Prove that the string 01000110111001 is in L.
- (b) Prove that #(0, w) = #(1, w) for every string $w \in L$.
- (c) Prove that *L* contains every string $w \in \{0, 1\}^*$ such that #(0, w) = #(1, w).

You may assume without proof that #(a, xy) = #(a, x) + #(a, y) for any symbol a and any strings x and y, or any other result proved in lecture, in lab, or in the lecture notes. Otherwise, your proofs must be formal and self-contained; in particular, they must invoke the recursive definition of the set L. Do not appeal to intuition!

2. Consider the following pair of mutually recursive functions on strings:

$$odds(w) := \begin{cases} \varepsilon & \text{if } w = \varepsilon \\ a \cdot evens(x) & \text{if } w = ax \end{cases} evens(w) := \begin{cases} \varepsilon & \text{if } w = \varepsilon \\ odds(x) & \text{if } w = ax \end{cases}$$

For example, the following derivation shows that evens(PARITY) = AIY:

$$evens(PARITY) = odds(ARITY)$$

$$= A \cdot evens(RITY)$$

$$= A \cdot odds(ITY)$$

$$= A \cdot (I \cdot evens(TY))$$

$$= A \cdot (I \cdot odds(Y))$$

$$= A \cdot (I \cdot (Y \cdot evens(\varepsilon)))$$

$$= A \cdot (I \cdot (Y \cdot \varepsilon))$$

$$= AIY$$

A similar derivation implies that odds(PARITY) = PRT.

- (a) Give a self-contained recursive definition for the function *evens* that does not involve the function *odds*.
- (b) Prove the following identity for all strings *w* and *x*:

$$evens(w \cdot x) = \begin{cases} evens(w) \cdot evens(x) & \text{if } |w| \text{ is even,} \\ evens(w) \cdot odds(x) & \text{if } |w| \text{ is odd.} \end{cases}$$

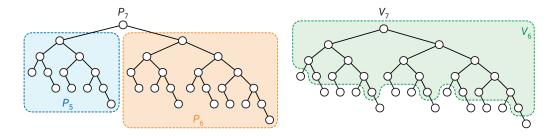

Again, you may assume without proof any result proved in lecture, in lab, or in the lecture notes. In particular, you may freely use the fact that concatenation is associative. Otherwise, your proofs must be formal and self-contained; in particular, they must invoke the recursive definitions of concatenation \bullet , length $|\cdot|$, and the *evens* and *odds* functions. Do not appeal to intuition!

*3. Practice only. Do not submit solutions.

For each non-negative integer n, we recursively define two binary trees P_n and V_n , called the nth Pingala tree and the nth $Virah\bar{a}nka$ tree, respectively.

- P_0 and V_0 are empty trees, with no nodes.
- P_1 and V_1 each consist of a single node.
- For any integer $n \ge 2$, the tree P_n consists of a root with two subtrees; the left subtree is a copy of P_{n-2} , and the right subtree is a copy of P_{n-1} .
- For any integer $n \ge 2$, the tree V_n is obtained from V_{n-1} by attaching a new right child to every leaf and attaching a new left child to every node that has only a right child.

The following figure shows the recursive construction of these two trees when n = 7.

Recall that the Fibonacci numbers are defined recursively as follows:

$$F_n = \begin{cases} 0 & \text{if } n = 0\\ 1 & \text{if } n = 1\\ F_{n-1} + F_{n-2} & \text{otherwise} \end{cases}$$

- (a) Prove that the tree P_n has exactly F_n leaves.
- (b) Prove that the tree V_n has exactly F_n leaves. [Hint: You need to prove a stronger result.]
- (c) Prove that the trees P_n and V_n are identical, for all $n \ge 0$.

[Hint: The hardest part of these proofs is developing the right language and notation.]

As in earlier problems, you may freely use any result that proved in lecture, in lab, or in the lecture notes. Otherwise your proofs must be formal and self-contained; in particular, they must invoke the recursive definitions of the trees P_n and V_n and the Fibonacci numbers F_n .

Solved Problems

4. For any string $w \in \{0, 1\}^*$, let swap(w) denote the string obtained from w by swapping the first and second symbols, the third and fourth symbols, and so on. For example:

$$swap(10110001101) = 01110010011.$$

The swap function can be formally defined as follows:

$$swap(w) := \begin{cases} \varepsilon & \text{if } w = \varepsilon \\ w & \text{if } w = \emptyset \text{ or } w = 1 \\ ba \bullet swap(x) & \text{if } w = abx \text{ for some } a, b \in \{\emptyset, 1\} \text{ and } x \in \{\emptyset, 1\}^* \end{cases}$$

(a) Prove that |swap(w)| = |w| for every string w.

Solution: Let *w* be an arbitrary string.

Assume |swap(x)| = |x| for every string x that is shorter than w.

There are three cases to consider (mirroring the definition of *swap*):

• If $w = \varepsilon$, then

$$|swap(w)| = |swap(\varepsilon)|$$
 because $w = \varepsilon$
 $= |\varepsilon|$ by definition of $swap$
 $= |w|$ because $w = \varepsilon$

• If w = 0 or w = 1, then

$$|swap(w)| = |w|$$
 by definition of $swap$

• Finally, if w = abx for some $a, b \in \{0, 1\}$ and $x \in \{0, 1\}^*$, then

$$|swap(w)| = |swap(abx)|$$
 because $w = abx$
 $= |ba \cdot swap(x)|$ by definition of $swap$
 $= |ba| + |swap(x)|$ because $|y \cdot z| = |y| + |z|$
 $= |ba| + |x|$ by the induction hypothesis
 $= 2 + |x|$ by definition of $|\cdot|$
 $= |ab| + |x|$ by definition of $|\cdot|$
 $= |ab \cdot x|$ because $|y \cdot z| = |y| + |z|$
 $= |abx|$ by definition of $|\cdot|$

In all cases, we conclude that |swap(w)| = |w|.

Rubric: 5 points: Standard induction rubric (scaled). This is more detail than necessary for full credit.

(b) Prove that swap(swap(w)) = w for every string w.

Solution: Let *w* be an arbitrary string.

Assume swap(swap(x)) = x for every string x that is shorter than w. There are three cases to consider (mirroring the definition of swap):

• If $w = \varepsilon$, then

$$swap(swap(w)) = swap(swap(\varepsilon))$$
 because $w = \varepsilon$
 $= swap(\varepsilon)$ by definition of $swap$
 $= \varepsilon$ by definition of $swap$
 $= w$ because $w = \varepsilon$

• If w = 0 or w = 1, then

$$swap(swap(w)) = swap(w)$$
 by definition of $swap$
= w by definition of $swap$

• Finally, if w = abx for some $a, b \in \{0, 1\}$ and $x \in \{0, 1\}^*$, then

```
swap(swap(w)) = swap(swap(abx))
                                                   because w = abx
               = swap(ba \cdot swap(x))
                                                by definition of swap
                = swap(ba \cdot z)
                                                  where z = swap(x)
                = swap(baz)
                                                    by definition of •
                = ab \cdot swap(z)
                                                by definition of swap
                = ab \cdot swap(swap(x))
                                                because z = swap(x)
                = ab \cdot x
                                         by the induction hypothesis
                                                    by definition of •
                =abx
                                                   because w = abx
                = w
```

In all cases, we conclude that swap(swap(w)) = w.

Rubric: 5 points: Standard induction rubric (scaled). This is more detail than necessary for full credit.

5. The *reversal* w^R of a string w is defined recursively as follows:

$$w^{R} := \begin{cases} \varepsilon & \text{if } w = \varepsilon \\ x^{R} \bullet a & \text{if } w = a \cdot x \end{cases}$$

A *palindrome* is any string that is equal to its reversal, like AMANAPLANACANALPANAMA, RACECAR, POOP, I, and the empty string.

(a) Give a recursive definition of a palindrome over the alphabet Σ .

Solution: A string $w \in \Sigma^*$ is a palindrome if and only if either

- $w = \varepsilon$, or
- w = a for some symbol $a \in \Sigma$, or
- w = axa for some symbol $a \in \Sigma$ and some palindrome $x \in \Sigma^*$.

Rubric: 2 points = $\frac{1}{2}$ for each base case + 1 for the recursive case. No credit for the rest of the problem unless this part is correct.

(b) Prove $w = w^R$ for every palindrome w (according to your recursive definition). You may assume the following facts about all strings x, y, and z:

- Reversal reversal: $(x^R)^R = x$
- Concatenation reversal: $(x \cdot y)^R = y^R \cdot x^R$
- Right cancellation: If $x \cdot z = y \cdot z$, then x = y.

Solution: Let *w* be an arbitrary palindrome.

Assume that $x = x^R$ for every palindrome x such that |x| < |w|.

There are three cases to consider (mirroring the definition of "palindrome"):

- If $w = \varepsilon$, then $w^R = \varepsilon$ by definition, so $w = w^R$.
- If w = a for some symbol $a \in \Sigma$, then $w^R = a$ by definition, so $w = w^R$.
- Finally, if w = axa for some symbol $a \in \Sigma$ and some palindrome $x \in P$, then

$$w^R = (a \cdot x \cdot a)^R$$
 because $w = axa$
 $= (x \cdot a)^R \cdot a$ by definition of reversal
 $= a^R \cdot x^R \cdot a$ by concatenation reversal
 $= a \cdot x^R \cdot a$ by definition of reversal
 $= a \cdot x \cdot a$ by the inductive hypothesis
 $= w$ because $w = axa$

In all three cases, we conclude that $w = w^R$.

Rubric: 4 points: standard induction rubric (scaled)

(c) Prove that every string w such that $w = w^R$ is a palindrome (according to your recursive definition).

Again, you may assume the following facts about all strings x, y, and z:

- Reversal reversal: $(x^R)^R = x$
- Concatenation reversal: $(x \cdot y)^R = y^R \cdot x^R$
- Right cancellation: If $x \cdot z = y \cdot z$, then x = y.

Solution: Let *w* be an arbitrary string such that $w = w^R$.

Assume that every string x such that |x| < |w| and $x = x^R$ is a palindrome.

There are three cases to consider (mirroring the definition of "palindrome"):

- If $w = \varepsilon$, then w is a palindrome by definition.
- If w = a for some symbol $a \in \Sigma$, then w is a palindrome by definition.
- Otherwise, we have w = ax for some symbol a and some *non-empty* string x. The definition of reversal implies that $w^R = (ax)^R = x^R a$.

Because x is non-empty, its reversal x^R is also non-empty.

Thus, $x^R = by$ for some symbol b and some string y.

It follows that $w^R = bya$, and therefore $w = (w^R)^R = (bya)^R = ay^Rb$.

 $\langle At this point, we need to prove that <math>a = b$ and that y is a palindrome.

Our assumption that $w = w^R$ implies that $bya = ay^Rb$.

The recursive definition of string equality immediately implies a = b.

Because a = b, we have $w = ay^R a$ and $w^R = aya$.

The recursive definition of string equality implies $y^R a = ya$.

Right cancellation implies $y^R = y$.

The inductive hypothesis now implies that y is a palindrome.

We conclude that w is a palindrome by definition.

In all three cases, we conclude that *w* is a palindrome.

Rubric: 4 points: standard induction rubric (scaled).

- 6. Let $L \subseteq \{0,1\}^*$ be the language defined recursively as follows:
 - The empty string ε is in L.
 - For any string $x \in L$, the strings 0101x and 1010x are also in L.
 - For all strings x and y such that xy ∈ L, the strings x00y and x11y are also in L.
 (In other words, inserting two consecutive 0s or two consecutive 1s anywhere in a string in L yields another string in L.)
 - These are the only strings in *L*.

Let *EE* denote the set of all strings $w \in \{0, 1\}^*$ such that #(0, w) and #(1, w) are both even.

(a) Prove that $L \subseteq EE$.

Solution: Let w be an arbitrary string in L. We need to prove that #(0, w) and #(1, w) are both even. Here I will prove only that #(0, w) is even; the proof that #(1, w) is even is symmetric.

Assume for every string $x \in L$ such that |x| < |w| that #(0, x) is even. There are several cases to consider, mirroring the definition of L.

- Suppose $w = \varepsilon$. Then #(0, w) = 0, and 0 is even.
- Suppose w = 0101x or w = 1010x for some string $x \in L$. The definition of # (applied four times) implies #(0, w) = #(0, x) + 2. The inductive hypothesis implies #(0, x) is even. We conclude that #(0, w) is even.
- Suppose w = x 00 y for some strings x and y such that $xy \in L$. Then

$$#(0, w) = #(0, x00y)$$

$$= #(0, x) + #(0, 00) + #(0, y)$$

$$= #(0, x) + #(0, y) + #(0, 00)$$

$$= #(0, xy) + 2$$

The induction hypothesis implies $\#(\emptyset, xy)$ is even. We conclude that $\#(\emptyset, w) = \#(\emptyset, xy) + 2$ is also even.

• Finally, suppose w = x11y for some strings x and y such that $xy \in L$. Then

$$#(0, w) = #(0, x11y)$$

$$= #(0, x) + #(0, 11) + #(0, y)$$

$$= #(0, x) + #(0, y)$$

$$= #(0, xy)$$

The induction hypothesis implies #(0, w) = #(0, xy) is even.

In all cases, we have shown that #(0, w) is even. Symmetric arguments imply that #(1, w) is even. We conclude that $w \in EE$.

Rubric: 5 points: standard induction rubric (scaled). Yes, this is enough detail for #(1, w). If

explicit proofs are given for both #(0, w) and #(1, w), grade them independently, each for $2\frac{1}{2}$ points.

(b) Prove that $EE \subseteq L$.

Solution: Let w be an arbitrary string in EE. We need to prove that $w \in L$. Assume that for every string $x \in EE$ such that |x| < |w|, we have $x \in L$. There are four (overlapping) cases to consider, depending on the first four symbols in w.

- Suppose |w| < 4. Then w must be one of the strings ε , 00, or 11; brute force inspection implies that every other string of length at most 3 (0, 1, 01, 10, 000, 001, 010, 011, 100, 101, 110, 111) has an odd number of 0s or an odd number of 1s (or both). All three strings ε , 00, and 11 are in L. In all other cases, we can assume that $|w| \ge 4$, so the "first four symbols of w" are well-defined.
- Suppose the first four symbols of w are $00\underline{00}$ or $00\underline{00}$ or $00\underline{00}$ or $00\underline{00}$ or $00\underline{00}$ or $01\underline{00}$ or $01\underline{00}$ or $10\underline{00}$ or $11\underline{00}$. Then w = x00y for some (possibly empty) strings x and y. Arguments in part (a) imply that #(0, xy) = #(0, w) 2 and #(1, xy) = #(1, w) are both even. Thus $xy \in EE$ by definition of EE. So the induction hypothesis implies $xy \in L$. We conclude that $w = x00y \in L$ by definition of L.
- Suppose the first four symbols of w are $00\underline{11}$ or $0\underline{11}0$ or $0\underline{11}1$ or $10\underline{11}$ or $\underline{11}00$ or $\underline{11}01$ or $1\underline{11}0$ or $\underline{11}11$.) After swapping 0s and 1s, the argument in the previous case implies that $w \in L$.
- Finally, suppose the first four symbols of w are 0101 or 1010; in other words, suppose w = 0101x or w = 1010x for some (possibly empty) string x. Then #(0,x) = #(0,w) 2 and #(1,x) = #(1,w) 2 are both even, so $x \in EE$ by definition. The induction hypothesis implies $x \in L$. We conclude that $w \in L$ by definition of L.

Each of the 16 possible choices for the first four symbols of w is considered in at least one of the last three cases.

In all cases, we conclude that $w \in L$.

Rubric: 5 points: standard induction rubric (scaled). This is not the only correct proof. This is not the only correct way to express this particular case analysis.
