# Routing

---

## ▶ Goals

- ▶ Capture the notion of “best” routes
- ▶ Propagate changes effectively
- ▶ Require limited information exchange

## ▶ Conceptually

- ▶ A network can be represented as a graph where each host/router is a node and each physical connection is a link

# Routing: Ideal Approach

---

- ▶ Maintain information about each link
- ▶ Calculate fastest path between each directed pair

For each direction, maintain:

- Bandwidth
- Latency
- Queueing delay

# Routing: Ideal Approach

---

## ▶ Problems

- ▶ Unbounded amount of information
- ▶ Queueing delay can change rapidly
- ▶ Graph connectivity can change rapidly

## ▶ Solution

- ▶ Dynamic
  - ▶ Periodically recalculate routes
- ▶ Distributed
  - ▶ No single point of failure
  - ▶ Reduced computation per node
- ▶ Abstract Metric
  - ▶ “Distance” may combine many factors
  - ▶ Use heuristics

# Routing Overview

---

## ▶ Algorithms

### ▶ Static shortest path algorithms

#### ▶ Bellman-Ford

- Based on local iterations

#### ▶ Dijkstra's algorithm

- Build tree from source

### ▶ Distributed, dynamic routing algorithms

#### ▶ Distance vector routing

- Distributed Bellman-Ford

#### ▶ Link state routing

- Implement Dijkstra's algorithm at each node

# Bellman-Ford Algorithm

---

- ▶ Based on repetition of iterations
  - ▶ For every node A and every neighbor B of A
    - ▶ Is the cost of the path ( $A \rightarrow B \rightarrow \dots \rightarrow \text{destination}$ ) smaller than the currently known cost from A to destination?
    - ▶ If YES
      - Make B the successor node for A
      - Update cost from A to destination
  - ▶ Can run iterations synchronously or all at once

# Bellman-Ford Algorithm

# Distance Vector Routing

---

- ▶ Distributed dynamic version of Bellman-Ford
- ▶ Each node maintains a table of
  - ▶  $\langle \text{destination, distance, successor} \rangle$
- ▶ Information acquisition
  - ▶ Assume nodes initially know cost to immediate neighbor
  - ▶ Nodes send  $\langle \text{destination, distance} \rangle$  vectors to all immediate neighbors
    - ▶ Periodically – seconds, minutes
    - ▶ Whenever vector changes – triggered update

# Distance Vector Routing

---

- ▶ When a route changes
  - ▶ Local failure detection
    - ▶ Control message not acknowledged
    - ▶ Timeout on periodic route update
  - ▶ Current route disappears
  - ▶ Newly advertised route is shorter than previous route

# Distance Vector Routing

---

## ► Problem

- Node X notices that its link to Y is broken
- Other nodes believe that the route through X is still good
- Mutual deception!

# Dijkstra's Algorithm

---

- ▶ Greedily grow set  $C$  of confirmed least cost paths
- ▶ Initially  $C = \{\text{source}\}$
- ▶ Loop  $N-1$  times
  - ▶ Determine the node  $M$  outside  $C$  that is closest to the source
  - ▶ Add  $M$  to  $C$  and update costs for each node  $P$  outside  $C$ 
    - ▶ Is the path (source  $\rightarrow \dots \rightarrow M \rightarrow P$ ) better than the previously known path for (source  $\rightarrow P$ )?
    - ▶ If YES
      - Update cost to reach  $P$

# Dijkstra's Algorithm

# Link State Routing

---

## ▶ Strategy

- ▶ Send all nodes information about directly connected links
- ▶ Status of links is flooded in link state packets (LSPs)

## ▶ Each LSP carries

- ▶ ID of node that created the LSP
- ▶ Vector of <neighbor, cost of link to neighbor> pairs for the node that created the LSP
- ▶ Sequence number
- ▶ Time-to-live (TTL)

## ▶ Each node maintains a list of (ideally all) LSP's and runs Dijkstra's algorithm on the list

# Link State Routing

---

- ▶ LSP must be delivered to all nodes
- ▶ Information acquisition via reliable flooding
  - ▶ Create local LSP periodically with increasing sequence number
  - ▶ Send local LSP to all immediate neighbors
  - ▶ Forward new LSP out on all other links
- ▶ What does “new” mean?
  - ▶ New sequence number
  - ▶ TTL accounts for wrapped sequence numbers
    - ▶ Decrement TTL for stored nodes

# Source Routing

---

- ▶ **Variant of link state routing**
  - ▶ Like link state, distribute network topology and compute shortest paths at source
  - ▶ ...but only at source, not every hop!

# Link State Routing

---

## ▶ Pros

- ▶ Stabilizes quickly, does not generate much traffic, responds to topology changes or node failures

## ▶ Cons

- ▶ Amount of information stored at each node is large

# LS vs. DV

---

- ▶ **DV**
  - ▶ Send everything you know to your neighbors
- ▶ **LS**
  - ▶ Send info about your neighbors to everyone
- ▶ **Message size**
  - ▶ Small with LS
  - ▶ Potentially large with DV
- ▶ **Message exchange**
  - ▶ LS:  $O(nE)$
  - ▶ DV: only to neighbors

# When the network just isn't there ...

---

- ▶ **Mesh networks**

- ▶ Core nodes are stable
- ▶ Paths may exist between a src/dst pair

- ▶ **Ad hoc networks**

- ▶ Group of cooperating nodes
- ▶ Nodes are mobile
- ▶ Paths eventual exist between a src/dst pair
- ▶ All nodes are routers

# Mesh Network

# Ad Hoc Networks

- ▶ Formed by wireless hosts that may be mobile
- ▶ Without (necessarily) using a pre-existing infrastructure
- ▶ Routes between nodes may potentially contain multiple hops
  - ▶ Mobility causes route changes

# Why Ad Hoc Networks ?

---

- ▶ Ease of deployment
- ▶ Speed of deployment
- ▶ Decreased dependence on infrastructure

# Many Variations

---

- ▶ **Fully Symmetric Environment**

- ▶ All nodes have identical capabilities and responsibilities

- ▶ **Asymmetric Capabilities**

- ▶ Transmission ranges and radios may differ
  - ▶ Battery life at different nodes may differ
  - ▶ Processing capacity may be different at different nodes
  - ▶ Speed of movement

- ▶ **Asymmetric Responsibilities**

- ▶ Only some nodes may route packets
  - ▶ Some nodes may act as leaders of nearby nodes (e.g., cluster head)

# Many Variations

---

- ▶ Traffic characteristics may differ in different ad hoc networks
  - ▶ Bit rate
  - ▶ Timeliness constraints
  - ▶ Reliability requirements
  - ▶ Unicast / multicast / geocast
  - ▶ Host-based addressing / content-based addressing / capability-based addressing
- ▶ May co-exist (and co-operate) with an infrastructure-based network

# Many Variations

---

- ▶ **Mobility characteristics**
  - ▶ Speed
  - ▶ Predictability
    - ▶ Direction of movement
    - ▶ Pattern of movement
  - ▶ Uniformity (or lack thereof) of mobility characteristics among different nodes

# Challenges

---

- ▶ Limited wireless transmission range
- ▶ Broadcast nature of the wireless medium
  - ▶ Hidden terminal problem
- ▶ Packet losses due to transmission errors
- ▶ Mobility-induced route changes
- ▶ Mobility-induced packet losses
- ▶ Battery constraints
- ▶ Potentially frequent network partitions
- ▶ Ease of snooping on wireless transmissions

# The Holy Grail

---

- ▶ **A one-size-fits-all solution**
  - ▶ Perhaps using an adaptive/hybrid approach that can adapt to situation at hand
- ▶ **Difficult problem**
- ▶ **Many solutions proposed trying to address a sub-space of the problem domain**

# Unicast Routing in Ad Hoc Networks

# Why is routing in wireless ad hoc networks different/difficult?

---

- ▶ **Link instability causes many routing issues**
  - ▶ Shortest hop routing often worst choice
  - ▶ Scarce bandwidth makes overhead conspicuous
  - ▶ Battery power a concern
  - ▶ Security and misbehavior ...
- ▶ **Host mobility**
  - ▶ Link failure/repair due to mobility may have different characteristics than those due to other causes
  - ▶ Rate of link failure/repair may be high when nodes move fast
- ▶ **New performance criteria may be used**
  - ▶ Route stability despite mobility
  - ▶ Energy consumption

# Routing in Mobile Networks

---

- ▶ Imagine hundreds of hosts moving
  - ▶ Routing algorithm needs to cope up with varying wireless channel and node mobility

# Unicast Routing Protocols

---

- ▶ **Many protocols have been proposed**
  - ▶ Some have been invented specifically for ad hoc networks
  - ▶ Others are adapted from wired network routing
- ▶ **No single protocol works well in all environments**
  - ▶ Some attempts made to develop adaptive protocols

# Routing Protocols

---

- ▶ **Proactive protocols**

- ▶ Determine routes independent of traffic pattern
- ▶ Traditional link-state and distance-vector routing protocols are proactive

- ▶ **Reactive protocols**

- ▶ Maintain routes only if needed

- ▶ **Hybrid protocols**

- ▶ Maintain routes to nearby nodes
- ▶ Discover routes for far away nodes

# Trade-Off

---

- ▶ Latency of route discovery

- ▶ Proactive protocols

- ▶ May have lower latency since routes are maintained at all times

- ▶ Reactive protocols

- ▶ May have higher latency because a route from X to Y will be found only when X attempts to send to Y

# Trade-Off

---

- ▶ **Overhead of route discovery/maintenance**
  - ▶ **Reactive protocols**
    - ▶ May have lower overhead since routes are determined only if needed
  - ▶ **Proactive protocols**
    - ▶ Can (but not necessarily) result in higher overhead due to continuous route updating
- ▶ Which approach achieves a better trade-off depends on the traffic and mobility patterns

# Flooding for Data Delivery

---

- ▶ **Sender**
  - ▶ Broadcasts data packet  $P$  to all its neighbors
- ▶ **Intermediate nodes**
  - ▶ Forward  $P$  to its neighbors
- ▶ **Sequence numbers**
  - ▶ Used to avoid the possibility of forwarding the same packet more than once
- ▶ **Destination**
  - ▶ Packet  $P$  reaches destination  $D$  provided that  $D$  is reachable from sender  $S$
  - ▶ Node  $D$  does not forward the packet

# Flooding for Data Delivery

---

nodes that have received packet

# Flooding for Data Delivery

# Flooding for Data Delivery

- ▶ Node H receives packet from two neighbors:  
potential for collision

# Flooding for Data Delivery

- ▶ Node C receives packet from G and H, but does not forward it again, because node C has **already forwarded that packet** once

# Flooding for Data Delivery

- ▶ Nodes J and K both broadcast packet to node D
  - ▶ Since nodes J and K are **hidden** from each other, their **transmissions may collide**

# Flooding for Data Delivery

- ▶ Nodes J and K both broadcast packet to node D  
=> Packet may not be delivered to node D at all, despite the use of flooding

# Flooding for Data Delivery

- ▶ Node D **does not forward** packet, because node D is the **intended destination**

# Flooding for Data Delivery

## ► Flooding completed

- Nodes **unreachable** from S do not receive packet (e.g., Z)
- Nodes for which all paths from S go through D also do not receive packet (example: N)

# Flooding for Data Delivery

- ▶ Flooding may deliver packets to too many nodes
- ▶ **worst case**, all nodes reachable from sender may receive the packet

# Flooding for Data Delivery: Advantages

---

- ▶ **Simplicity**
- ▶ **Efficiency**
  - ▶ Low rate of information transmission
    - ▶ Overhead of explicit route discovery/maintenance incurred by other protocols is relatively higher
    - ▶ For example, when nodes transmit small data packets relatively infrequently, and many topology changes occur between consecutive packet transmissions
- ▶ **Potentially higher reliability of data delivery**
  - ▶ Because packets may be delivered to the destination on multiple paths

# Flooding for Data Delivery: Disadvantages

---

- ▶ **Potentially, very high overhead**
  - ▶ Data packets may be delivered to too many nodes who do not need to receive them
- ▶ **Potentially lower reliability of data delivery**
  - ▶ Flooding uses broadcasting
    - ▶ Hard to implement reliable broadcast
      - Broadcast in IEEE 802.11 MAC is unreliable
    - ▶ e.g., nodes J and K may transmit to node D simultaneously, resulting in loss of the packet
    - ▶ In this case, destination would not receive the packet at all

# Flooding of Control Packets

---

- ▶ Many protocols perform (potentially limited) flooding of control packets, instead of data packets
  - ▶ The control packets are used to discover routes
  - ▶ Discovered routes are subsequently used to send data packet(s)
- ▶ Overhead of control packet flooding is amortized over data packets transmitted between consecutive control packet floods

# Dynamic Source Routing (DSR)

---

## ▶ Route Discovery

- ▶ When node S wants to send a packet to node D, but does not know a route to D, node S initiates a route discovery
- ▶ Source node S floods Route Request (RREQ)
- ▶ Each node appends own identifier when forwarding RREQ

# Route Discovery in DSR

---

# Route Discovery in DSR

- $[X,Y]$ : list of identifiers appended to RREQ

# Route Discovery in DSR

- ▶ Node H receives packet RREQ from two neighbors: **potential for collision**

# Route Discovery in DSR

- ▶ Node C receives RREQ from G and H
  - ▶ Node C does not forward it again, because node C has **already forwarded RREQ** once

# Route Discovery in DSR

- ▶ Nodes J and K both broadcast RREQ to node D
- ▶ Since nodes J and K are **hidden** from each other, their **transmissions may collide**

# Route Discovery in DSR

- ▶ Node D **does not forward** RREQ, because node D is the **intended target** of the route discovery

# Route Reply in DSR

## ► Destination D

- On receiving the first RREQ, send a Route Reply (RREP)
- RREP is sent on a route obtained by reversing the route appended to received RREQ
- RREP includes the route from S to D on which RREQ was received by node D

# Route Reply in DSR

---

## ▶ Route Reply

### ▶ Bi-directional links

- ▶ Reverse route in Route Request (RREQ)
- ▶ RREQ should be forwarded only if received on a link that is known to be bi-directional

### ▶ Unidirectional (asymmetric) links

- ▶ RREP may need a route discovery for S from node D
  - Route Reply is piggybacked on the Route Request from D
- ▶ Unless node D already knows a route to node S

## ▶ IEEE 802.11 MAC

- ▶ Links must be bi-directional (since ACK is used)

# Dynamic Source Routing (DSR)

---

- ▶ **On receiving RREP**
  - ▶ Cache the route included in the RREP
- ▶ **Sending**
  - ▶ The entire route is included in the packet header
  - ▶ Hence the name source routing
- ▶ **Intermediate nodes**
  - ▶ Use the source route included in a packet to determine to whom a packet should be forwarded

# Data Delivery in DSR

- ▶ Packet header size grows with route length

# When to Perform a Route Discovery

---

- ▶ When node S wants to send data to node D, but does not know a valid route node D

# DSR Optimization: Route Caching

---

## ▶ Caching

- ▶ Each node caches a new route it learns by any means
- ▶ Snooping
  - ▶ A node may also learn a route when it overhears Data packets

## ▶ Use of Route Caching

- ▶ Broken routes
  - ▶ Use another route from the local cache
  - ▶ Otherwise, initiate new route discovery
- ▶ Intermediate response
  - ▶ On receiving a Route Request for some node D
    - Node X can send a Route Reply if node X knows a route to node D
- ▶ Use of route cache
  - ▶ Speed up route discovery
  - ▶ Reduce propagation of route requests

# Use of Route Caching

---

- ▶ **Broken routes**

- ▶ Use another route from the local cache
- ▶ Otherwise, initiate new route discovery

- ▶ **Intermediate response**

- ▶ On receiving a Route Request for some node D
  - ▶ Node X can send a Route Reply if node X knows a route to node D

- ▶ **Use of route cache**

- ▶ Speed up route discovery
- ▶ Reduce propagation of route requests

# Use of Route Caching

- ▶ **[P,Q,R]** Represents cached route at a node
  - ▶ DSR maintains the cached routes in a tree format

# Use of Route Caching: Speed up Route Discovery

- ▶ **Z** sends a route request for node **C**
  - ▶ Node **K** sends back a route reply **[Z,K,G,C]** to node **Z** using a locally cached route

# Use of Route Caching: Reduce of Route Requests

- ▶ No link between D and Z
  - ▶ Route Reply (RREP) from node K **limits flooding** of RREQ
  - ▶ In general, the reduction may be less dramatic.

# Route Error (RERR)

- ▶ When attempt to forward the data packet S (with route SEFJD) on J-D fails
  - ▶ J sends a route error to S along J-F-E-S
  - ▶ Nodes hearing RERR update their route cache to remove link J-D

# Route Caching: Beware!

---

- ▶ **Stale caches**
  - ▶ Can adversely affect performance
- ▶ **Timeliness**
  - ▶ With passage of time and host mobility, cached routes may become invalid
- ▶ **Know when to give up**
  - ▶ A sender host may try several stale routes (obtained from local cache, or replied from cache by other nodes), before finding a good route

# Dynamic Source Routing: Advantages

---

## ▶ On-demand

- ▶ Routes maintained only between nodes that need to communicate
- ▶ Reduces overhead of route maintenance

## ▶ Route caching

- ▶ Can further reduce route discovery overhead
- ▶ A single route discovery may yield many routes to the destination, due to intermediate nodes replying from local caches

# Dynamic Source Routing: Disadvantages

---

## ▶ Size

- ▶ Packet header size grows with route length

## ▶ Packets

- ▶ Flood of route requests may reach all nodes

## ▶ Timing

- ▶ Must avoid route requests collisions
  - ▶ Insertion of random delays before forwarding RREQ
- ▶ Route Reply Storm problem
  - ▶ Too many nodes reply using local cache
  - ▶ Prevent a node from sending RREP if it hears another RREP with a shorter route

# Dynamic Source Routing: Disadvantages

---

## ▶ Pollution

- ▶ An intermediate node may send Route Reply using a stale cached route
- ▶ Need some mechanism to purge (potentially) invalid cached routes

## ▶ For some proposals for cache invalidation

- ▶ Static timeouts
- ▶ Adaptive timeouts based on link stability

# Flooding of Control Packets

---

- ▶ How to reduce the scope of the route request flood ?
  - ▶ LAR
- ▶ How to reduce redundant broadcasts ?
  - ▶ The Broadcast Storm Problem

# Location-Aided Routing (LAR)

---

- ▶ **Exploit location information to limit scope of flood**
  - ▶ Location information may be obtained using GPS
- ▶ **Expected Zone**
  - ▶ A region that is expected to hold the current location of the destination
  - ▶ Determined based on potentially old location information and knowledge of the destination's speed
- ▶ **Route requests limited to a Request Zone that contains the Expected Zone and location of the sender node**

# Expected Zone in LAR

---

- ▶  $X$  = last known location of node D, at time  $t_0$
- ▶  $Y$  = location of node D at current time  $t_1$ , unknown to node S
- ▶  $r = (t_1 - t_0) * \text{estimate of D's speed}$

**Expected Zone**

# Request Zone in LAR

---

# LAR

---

## ▶ Zone

- ▶ Explicitly specified in the route request
- ▶ Each node must know its physical location to determine whether it is within the request zone

## ▶ Forwarding

- ▶ Only nodes within the request zone forward route requests

## ▶ Failure

- ▶ Initiate another route discovery (after a timeout) using a larger request zone
- ▶ the larger request zone may be the entire network

## ▶ Rest of route discovery protocol similar to DSR

# Location Aided Routing (LAR)

---

## ▶ Advantages

- ▶ Reduces the scope of route request flood
- ▶ Reduces overhead of route discovery

## ▶ Disadvantages

- ▶ Nodes need to know their physical locations
- ▶ Does not take into account possible existence of obstructions for radio transmissions

# Broadcast Storm Problem

---

- ▶ When node A broadcasts a route query, nodes B and C both receive it
  - ▶ B and C both forward to their neighbors
  - ▶ B and C transmit at about the same time since they are reacting to receipt of the same message from A
  - ▶ This results in a high probability of collisions

# Broadcast Storm Problem

---

## ► Redundancy

- A given node may receive the same route request from too many nodes, when one copy would have sufficed
- Node D may receive from nodes B and C

# Solutions for Broadcast Storm

---

## ▶ Probabilistic scheme

- ▶ Re-broadcast (forward) the request with probability  $p$
- ▶ Re-broadcasts by different nodes should be staggered by using a collision avoidance technique
- ▶ Reduce the probability that nodes B and C would forward a packet simultaneously

# Solutions for Broadcast Storm

---

## ▶ Counter-Based Scheme

- ▶ If node E hears more than  $k$  neighbors broadcasting a given route request, before it can itself forward it, then node E will not forward the request

## ▶ Intuition

- ▶  $k$  neighbors together have probably already forwarded the request to all of E's neighbors

# Solutions for Broadcast Storm

---

## ► Distance-Based Scheme

- If node E hears RREQ broadcasted by some node Z within physical distance  $d$ , then E will not re-broadcast the request

## ► Intuition

- Z and E are close, so transmission areas covered by Z and E are not very different

# Summary: Broadcast Storm Problem

---

- ▶ Flooding is used in many protocols, such as Dynamic Source Routing (DSR)
- ▶ Problems associated with flooding
  - ▶ Collisions
    - ▶ May be reduced by “jittering” (waiting for a random interval before propagating the flood)
  - ▶ Redundancy
    - ▶ May be reduced by selectively re-broadcasting packets from only a subset of the nodes

# Ad Hoc On-Demand Distance Vector Routing (AODV)

---

- ▶ **Source routing**

- ▶ Large headers
- ▶ Particularly when data contents of a packet are small

- ▶ **AODV**

- ▶ Maintaining routing tables at the nodes
- ▶ Routes are maintained only between nodes which need to communicate

# AODV

---

- ▶ **Route Requests (RREQ)**
  - ▶ Forwarded in a manner similar to DSR
- ▶ **Routes**
  - ▶ When a node re-broadcasts a Route Request, it sets up a reverse path pointing towards the source
  - ▶ AODV assumes symmetric (bi-directional) links
- ▶ **Destination**
  - ▶ Destination replies to Route Request with a Route Reply
- ▶ **Route Reply**
  - ▶ Follows reverse path set-up by Route Request

# Route Requests in AODV

---

# Route Requests in AODV

Broadcast transmission

# Route Requests in AODV

---

# Reverse Path Setup in AODV

---

# Reverse Path Setup in AODV

- ▶ Node D **does not forward** RREQ, because node D is the **intended target** of the RREQ

# Route Reply in AODV

# Route Reply in AODV

---

- ▶ **Intermediate node reply**
  - ▶ Send a Route Reply (RREP) if it knows a more recent path than the one previously known to sender
- ▶ **Sequence Numbers**
  - ▶ Destination sequence numbers are used to determine age
- ▶ **Fewer intermediate replies than DSR**
  - ▶ A new Route Request for a destination is assigned a higher destination sequence number
  - ▶ An intermediate node that knows a route with a smaller sequence number cannot send Route Reply

# Forward Path Setup in AODV

- ▶ Forward links are setup when RREP travels along the reverse path

# Data Delivery in AODV

- ▶ Routing table entries used to forward data packet
- ▶ Route is *not* included in packet header

# Timeouts

---

- ▶ Routing table entries

- ▶ Reverse Paths

- ▶ Purged after a timeout interval
    - ▶ Timeout should be long enough to allow RREP to come back

- ▶ Forward Paths

- ▶ If no is data being sent using a particular routing table entry
      - Entry is deleted from the routing table (even if the route may actually still be valid)

# Link Failure Reporting

---

## ▶ Link Failure

- ▶ When the next hop link in a routing table entry breaks, all active neighbors are informed
- ▶ Active neighbors
  - ▶ Any neighbor that sent a packet within `active_route_timeout` interval which was forwarded using that entry

## ▶ Link failures

- ▶ Propagated by means of Route Error messages
- ▶ Also update destination sequence numbers

# Link Failure Detection

---

- ▶ **Hello messages**

- ▶ Neighboring nodes periodically exchange hello message
- ▶ Absence of hello message is used as an indication of link failure

- ▶ **Alternatively**

- ▶ Failure to receive several MAC-level acknowledgement may be used as an indication of link failure

# Why Sequence Numbers in AODV

- ▶ To avoid using old/broken routes
  - ▶ To determine which route is newer
- ▶ To prevent formation of loops

- ▶ RERR sent by C is lost
  - ▶ A does not know about failure of link C-D
- ▶ C performs a route discovery for D
  - ▶ Node A receives the RREQ (say, via path C-E-A)
- ▶ Node A replies since A knows a route to D via node B
- ▶ Results in a loop (for instance, C-E-A-B-C )

# Why Sequence Numbers in AODV

---

# Optimization: Expanding Ring Search

---

- ▶ **Route Requests**

- ▶ Initially sent with small Time-to-Live (TTL) field, to limit propagation
- ▶ DSR also includes a similar optimization

- ▶ **If no Route Reply is received**

- ▶ Larger TTL

# Summary: AODV

---

- ▶ Routes need not be included in packet headers
- ▶ Nodes maintain routing tables
  - ▶ Entries only for routes that are in active use
- ▶ At most one next-hop per destination maintained at each node
  - ▶ DSR may maintain several routes for a single destination
- ▶ Unused routes expire even if topology does not change

# Routing Metrics

# Power-Aware Routing

---

- ▶ Define optimization criteria as a function of energy consumption
- ▶ Examples
  - ▶ Minimize energy consumed per packet
  - ▶ Minimize time to network partition due to energy depletion
  - ▶ Maximize duration before a node fails due to energy depletion

# Power-Aware Routing

---

- ▶ Assign a weight to each link
- ▶ Weight of a link may be a function of
  - ▶ Energy consumed when transmitting a packet
  - ▶ Residual energy level
  - ▶ Low residual energy level may correspond to a high cost
- ▶ Prefer a route with the smallest aggregate weight

# Link Stability-Based Routing

---

## ▶ Idea

- ▶ A node  $X$  re-broadcasts a Route Request received from  $Y$  only if the  $(X,Y)$  link is deemed to have a strong signal stability

## ▶ Signal stability

- ▶ Evaluated as a moving average of the signal strength of packets received on the link in recent past

## ▶ Alternative approach

- ▶ Assign a cost as a function of signal stability

# Connection Stability-Based Routing

---

- ▶ Only utilize links that have been stable for some minimum duration
  - ▶ If a link has been stable beyond some minimum threshold
    - ▶ It is likely to be stable for a longer interval
  - ▶ If it has not been stable longer than the threshold
    - ▶ It may soon break (could be a transient link)
- ▶ Prefer paths with high aggregate stability

# Expected Transmission Count (ETX)

---

- ▶ **Link Metric**

- ▶ Fewest expected retransmissions
- ▶ Probe packets measure the packet delivery ratio in both forward and reverse directions

- ▶ **Path Metric**

- ▶ Sum of the individual link ETX values

# Expected Transmission Count (ETX)

---

- ▶ Forward delivery ratio = probability of a packet arriving at the destination
- ▶ Reverse delivery ratio = probability of a receiver's acknowledgment (ACK) arriving back at the sender.
- ▶ Link ETX =  $1 / (\text{Forward delivery ratio} \times \text{Reverse delivery ratio})$

# Expected Transmission Count (ETX)

---

## ▶ Strength

- ▶ Significant improvement over simple hop-count metrics by preferring reliable, low-loss links.

## ▶ Limitation

- ▶ Designed for single-radio networks
- ▶ Does not account for differences in link bandwidth or the effects of inter-channel interference in multi-radio networks

# IEEE 802.11s: WLAN Mesh

---

## ▶ Routing

### ▶ Hybrid Wireless Mesh Protocol

- ▶ Ad hoc On-Demand Distance Vector (AODV) Routing
- ▶ Tree-based routing

### ▶ Metrics

- ▶ Airtime Link Metric (ALM)
  - Time spent transmitting data and the packet error rate on a link.

# Weighted Cumulative Expected Transmission Time (WCETT)

---

## ▶ Goal

- ▶ Minimize total expected transmission time.

## ▶ Metric

### ▶ Link Metric

- ▶ Expected Transmission Time (ETT), which incorporates both the link loss rate and bandwidth
- ▶  $\text{Link ETT} = (\text{Link ETX}) * (\text{Packet Size} / \text{Bandwidth})$

### ▶ Intra-channel interference

- ▶ The sum of the Expected Transmission Times (ETTs) of links that share the same wireless channel

### ▶ Path Metric:

- ▶ The cumulative ETT of all links on the path
