University of Illinois at Urbana-Champaign (USA)

## Executability Conditions

A functional module `fmod`  $(\Sigma, E)$  `endfm` with constructor subsignature  $\Omega \subseteq \Sigma$  satisfying: (1) **Unique termination**, (2) **Sufficient Completeness** and (3) **Sort Preservation**, and, also,  $(\forall t \in T_\Omega) t!_{\vec{E}} = t$ , has a canonical term algebra  $\mathbb{C}_{\Sigma/E}$  as its **semantics**.

Conditions (1)–(3), plus requirement  $(\forall t \in T_\Omega) t!_{\vec{E}} = t$ , can best be understood by noting that the `red` command mapping  $t \in T_\Sigma$  to  $t!_{\vec{E}} \in T_\Omega$  is just **rewriting  $t$  to termination** with the rules  $\vec{E}$ .

But a functional module can have **axioms**  $B$ . That is, it can be of the form `fmod`  $(\Sigma, E \cup B)$  `endfm`. Then, the `red` command simplifies  $t \in T_\Sigma$  to  $t!_{\vec{E}/B} \in T_\Omega$  with the rules  $\vec{E}$  **modulo**  $B$ .

What **executability conditions** ensure that  $\mathbb{C}_{\Sigma/E,B}$  **exists** for `fmod`  $(\Sigma, E \cup B)$  `endfm` **in general**? They will be executability requirements on the **rewrite theory**  $(\Sigma, B, \vec{E})$ .

## Executability Conditions (II)

In terms of the rewrite theory  $(\Sigma, B, \vec{E})$ ,

- ① **Unique Termination** will follow from  $\vec{E}$  being:
  - **terminating** modulo  $B$ , and
  - **confluent** modulo  $B$
- ② **Sufficiently Completeness** will follow from  $\vec{E}$  being so modulo  $B$ , and
- ③ **Sort Preservation** will follow from  $\vec{E}$  being **sort decreasing**.

The requirement  $(\forall t \in T_\Omega) t!_{\vec{E}/B} = t$  **will not be needed**: it was just a simplifying assumption. And we will make explicit an **implicit assumption on variables** in the rules  $\vec{E}$  essential for executability.

Under the above executability requirements we will then define the **canonical term algebra**  $\mathbb{C}_{\Sigma/E,B}$  of a functional module  $\text{fmod}(\Sigma, E \cup B)$   $\text{endfm}$  with constructors  $\Omega \subseteq \Sigma$  in full generality.

## No Extra Variables in Righthand Sides

Consider the rule  $0 \rightarrow x * 0$ . This rule is **problematic**: we have to **guess** how to instantiate the variable  $x$  in  $x * 0$  before applying it, and there is an infinite number of instantiations for  $x$ .

Instead, the rule  $x * 0 \rightarrow 0$  can be applied without problems, since the **same** substitution obtained by matching for the lefthand side can be **reused** to generate the righthand side replacement.

Therefore, for any functional module `fmod ( $\Sigma, E \cup B$ ) endfm` and associated rewrite theory  $(\Sigma, B, \vec{E})$  we will require:

*For each  $t \rightarrow t' \in \vec{E}$ , **any variable  $x$  occurring in  $t'$  must also occur in  $t$** , i.e.,  $\text{vars}(t') \subseteq \text{vars}(t)$ .*

## Sort Decreasingness

Another important requirement on  $(\Sigma, B, \vec{E})$  is:

(SD) **Sort-decreasingness**: For each  $t \rightarrow t' \in \vec{E}$ ,  $s \in S$ , and each substitution  $\theta$  we have  $t\theta : s \Rightarrow t'\theta : s$ .

where  $t : s$  abbreviates  $t \in T_{\Sigma, s}$ . Prove by well-founded induction on the context  $C$  below which a rewrite  $C[t\theta] \rightarrow_{\vec{E}} C[t'\theta]$  takes place, that under condition (SD), if  $u \rightarrow_{\vec{E}} v$ , then  $u : s \Rightarrow v : s$ .

To see why without sort-decreasingness things can go wrong, let  $\Sigma$  have sorts  $C$  and  $D$  with  $C < D$ , a constant  $c$  of sort  $C$ , a constant  $d$  of sort  $D$ , and a subsort-overloaded unary function  $f : C \rightarrow C$ ,  $f : D \rightarrow D$ . Let  $B = \emptyset$  and  $\vec{E} = \{c \rightarrow d, f(f(x : C)) \rightarrow f(x : C)\}$ . With the second rule  $f(f(c))$  rewrites to  $f(c)$ , and then to  $f(d)$  with the first rule. But if we apply the first rule to  $f(f(c))$  we get  $f(f(d))$ , **which cannot be further rewritten** because **sort information has been lost!**

## Checking Sort-Decreasingness

Sort decreasingness can be easily checked, since we do not need to check it on the (infinite) set of all substitutions  $\theta$ . If

$\{x_1 : s_1, \dots, x_n : s_n\} = \text{vars}(t \rightarrow t')$ , we only need to check it on the **finite** set of substitutions of the form

$\{x_1 : s_1 \mapsto x'_1 : s'_1, \dots, x_n : s_n \mapsto x'_n : s'_n\}$ ,  $s'_i \leq s_i$ ,  $1 \leq i \leq n$ , called the **sort specializations** of the variables  $\{x_1 : s_1, \dots, x_n : s_n\}$ .

For example, for sorts  $\text{Nat} < \text{Set}$ , with  $_ \cup _$  set union, the rule  $x \rightarrow x \cup x$ , with  $x : \text{Set}$ , is **not** sort-decreasing, since for the sort specialization  $\{x : \text{Set} \mapsto x' : \text{Nat}\}$  we have  $ls(x') = \text{Nat} < \text{Set} = ls(x' \cup x')$ .

**Exercise.** For  $\Sigma$  preregular, prove that the rules  $\vec{E}$  are sort decreasing iff for each  $t \rightarrow t'$  in  $\vec{E}$  and for each sort specialization  $\rho$  (a fine number of  $\rho$ 's if  $(S, <)$  is finite) we have:  $ls(t\rho) \geq ls(t'\rho)$ .

## $B$ -Preregular Signatures

Recall that if  $\Sigma$  is **preregular** each term  $t$  has a least sort  $ls(t)$ . For axioms  $B$  we want the strongest property: that  $\Sigma$  is  **$B$ -preregular**, i.e., (1)  $\Sigma$  is preregular, and (2)  $t =_B t'$  implies  $ls(t) = ls(t')$ .

How can we check that  $\Sigma$  is  $B$ -preregular? Very easily. Assume all axioms  $B$  are such that for each  $(u = v) \in B$  we have  $vars(u) = vars(v)$ . Now consider the following:

### Theorem

*For  $\Sigma$  preregular and  $\Sigma$ -axioms  $B$  as above,  $\Sigma$  is  **$B$ -preregular** iff the rewrite theory  $(\Sigma, \vec{B} \cup \overleftarrow{B})$  is sort decreasing.*

The theorem follows easily from the properties of sort-decreasing rules stated in previous slides. Furthermore, it can be effectively checked for each  $(u = v) \in B$  using its sort specializations.

Maude automatically checks that  $\Sigma$  is  $B$ -preregular and gives a warning if the property fails.

# The Algebra $\mathbb{T}_{\Sigma/B}$

For  $\Sigma$   **$B$ -preregular** we can easily define the algebra  $\mathbb{T}_{\Sigma/B}$ , whose elements are  $B$ -equivalence classes  $[t]_B$  of terms modulo  $=_B$ , i.e.,  $t' \in [t]_B \Leftrightarrow t =_B t'$ . Specifically,  $\mathbb{T}_{\Sigma/B} = (T_{\Sigma/B}, -\mathbb{T}_{\Sigma/B})$ , where, abbreviating  $[t]_B$  to just  $[t]$ , we define:

- $T_{\Sigma/B} = \{T_{\Sigma,s}/=_B\}_{s \in S}$ , with  $T_{\Sigma,s}/=_B$  written  $T_{\Sigma/B,s}$ .
- For  $a : \rightarrow s$  in  $\Sigma$ ,  $a_{\mathbb{T}_{\Sigma/B}} = [a] \in T_{\Sigma/B,s}$ .
- For  $f : s_1 \dots s_n \rightarrow s$  in  $\Sigma$ ,  $f_{\mathbb{T}_{\Sigma/B}} : T_{\Sigma/B,s_1} \times \dots \times T_{\Sigma/B,s_n} \ni ([t_1], \dots, [t_n]) \mapsto [f(t_1, \dots, t_n)] \in T_{\Sigma/B,s}$ .

Note that the definition of  $f_{\mathbb{T}_{\Sigma/B}}$  **does not depend** on the **choice** of the  $t_1, \dots, t_n$ , since if  $t_i =_B t'_i$ ,  $1 \leq i \leq n$ , then we have:  $f(t_1, \dots, t_n) =_B f(t'_1, \dots, t'_n)$ , since we can build a proof from the proofs of  $t_i =_B t'_i$ ,  $1 \leq i \leq n$ .

## Determinism

Another requirement on  $(\Sigma, B, \vec{E})$  is **determinism**: if a term  $t$  is simplified by  $\vec{E}$  modulo  $B$  to two different terms  $u$  and  $v$ , and  $u \neq_B v$ , then  $u$  and  $v$  can always be **further simplified** by  $\vec{E}$  modulo  $B$  to a common term  $w$ .

This implies (Exercise!) that if  $t \xrightarrow{\star}_{\vec{E}/B} u$  and  $t \xrightarrow{\star}_{\vec{E}/B} v$ , and  $u$  and  $v$  cannot be further simplified by  $\vec{E}$  modulo  $B$ , then we must have  $u =_B v$ . This is the idea of **determinism**: if rewriting with  $\vec{E}$  modulo  $B$  yields a fully simplified answer, then that answer must be **unique** modulo  $B$ .

That is, modulo the axioms  $B$ , the final result of rewriting a term  $t$  with the rules  $\vec{E}$  modulo  $B$  should **not** depend on the particular order in which the rewrites have been performed.

# Determinism = Confluence

Determinism is captured by **confluence**. The rules  $\vec{E}$  of  $(\Sigma, B, \vec{E})$  are **confluent modulo**  $B$  iff for each  $t \in T_{\Sigma(Y)}^{\circ}$ , whenever  $t \xrightarrow{\vec{E}/B}^{\star} u$ ,  $t \xrightarrow{\vec{E}/B}^{\star} v$ , there is a  $w \in T_{\Sigma(Y)}^{\circ}$  such that  $u \xrightarrow{\vec{E}/B}^{\star} w$  and  $v \xrightarrow{\vec{E}/B}^{\star} w$ . This can be described diagrammatically (dashed arrows denote existential quantification):

$\vec{E}$  is **ground confluent modulo**  $B$  if this holds for all  $t \in T_{\Sigma}^{\circ}$ .

# Termination

## Definition

For the rewrite theory  $(\Sigma, B, \vec{E})$ , rules  $\vec{E}$  are called **terminating** modulo  $B$  iff  $\rightarrow_{\vec{E}/B}$  is well-founded.  $\vec{E}$  is called **weakly terminating** modulo  $B$  iff any  $t \in T_{\Sigma(Y)}^{\circ}$  has a  $\vec{E}/B$ -**normal form**, i.e.,  $\exists v \in T_{\Sigma(Y)}^{\circ}$  s.t.  $t \rightarrow_{\vec{E}/B}^{\star} v \wedge \nexists w \in T_{\Sigma(Y)}^{\circ}$  s.t.  $v \rightarrow_{\vec{E}/B} w$ .  
**(Notation:**  $t \rightarrow_{\vec{E}/B}^! v$ **).**

If  $(\Sigma, B, \vec{E})$  is ground confluent and terminating modulo  $B$ , each  $t \in T_{\Sigma}$  reduces to an  $\vec{E}/B$ -normal form denoted  $t!_{\vec{E}/B}$ , and  $t!_{\vec{E}/B}$  is **unique** modulo  $B$ , i.e.,  $[t!_{\vec{E}/B}]$  is unique. Furthermore, if  $\Sigma$  is  $B$ -**preregular**, and  $\vec{E}$  is **sort-decreasing**, both **Unique Termination** and **Sort Preservation** hold, and we have an  $S$ -sorted **function**:

$$-!_{\vec{E}/B} : T_{\Sigma} \ni t \mapsto [t!_{\vec{E}/B}] \in T_{\Sigma/B}$$

## Joinability and the Church-Rosser Property

Call two terms  $t, t' \in T_{\Sigma(Y)}^{\circ}$  **joinable** with  $\vec{E}$  modulo  $B$ , denoted  $t \downarrow_{\vec{E}/B} t'$ , iff  $(\exists w \in T_{\Sigma(Y)}^{\circ}) t \rightarrow_{\vec{E}/B}^{\star} w \wedge t' \rightarrow_{\vec{E}/B}^{\star} w$ .

**Exercise.** Prove that if  $(\Sigma, E \cup B)$  is an order-sorted equational theory whose rules  $\vec{E}$  are confluent modulo  $B$ , then the following equivalence, called the **Church-Rosser property**, holds for any two terms  $t, t' \in T_{\Sigma(Y)}^{\circ}$ :

$$(\dagger) \quad t =_{E \cup B} t' \Leftrightarrow t \downarrow_{\vec{E}/B} t'$$

Prove that if  $\vec{E}$  is also terminating modulo  $B$  we also have:

$$(\ddagger) \quad t =_{E \cup B} t' \Leftrightarrow t!_{\vec{E}/B} =_B t'!_{\vec{E}/B}$$

Since  $=_B$  (with  $B, A, C, U$  axioms) is **decidable**, we can **decide**  $t =_{E \cup B} t'$  by deciding  $t!_{\vec{E}/B} =_B t'!_{\vec{E}/B}$ , which we can do in Maude by typing: `red t == t'`.  $(\dagger)$  **reduces** equational deduction to **rewriting**, and  $(\ddagger)$  makes it **decidable**.

## Subsignatures and Constructor Subsignatures

Before defining sufficient completeness we make more precise the notions of subsignature and constructor subsignature.

### Definition

An order-sorted signature  $\Sigma' = ((S', <'), F', G')$ ,  $\Sigma'$  is called a **subsignature** of an order-sorted signature  $\Sigma = ((S, <), F, G)$ , denoted  $\Sigma' \subseteq \Sigma$ , iff:

- 1  $S' \subseteq S$ ,  $<' \subseteq <$ , and  $F' \subseteq F$ .
- 2  $G' \subseteq G$ , i.e., for each  $(f' : w' \rightarrow s') \in G'$  we have  $(f' : w' \rightarrow s') \in G$ .

If  $S' = S$  and  $<' = <$  we say that  $\Sigma' \subseteq \Sigma$  on **the same sort poset**.

In a functional module `fmod ( $\Sigma, E \cup B$ ) endfm`, the `ctor` declaration defines a subsignature  $\Omega \subseteq \Sigma$  on the same sort poset  $(S, <)$ , called the **constructor subsignature**.

# Sufficient Completeness Defined

## Definition

Let the rewrite theory  $(\Sigma, B, \vec{E})$  be terminating, and  $\Omega \subseteq \Sigma$  a subsignature inclusion, where  $\Omega$  has the same poset of sorts as  $\Sigma$ . We call the rules  $\vec{E}$  **sufficiently complete modulo**  $B$  with respect to the **constructor subsignature**  $\Omega$  iff for each  $t \in T_\Sigma$  and each  $\vec{E}/B$ -normal form of  $t$ , i.e., each  $u \in T_\Sigma$  s.t.  $t \rightarrow!_{\vec{E}/B} u$ , we have  $u \in T_\Omega$ .

## More on Sufficient Completeness

If  $\Sigma^\square$  is kind-complete, then the above requirement that for each  $t \in T_\Sigma$ , if  $t \rightarrow!_{\vec{E}/B} u$  then  $u \in T_\Omega$  should apply only to  $t \in T_{\Sigma,s}$  with  $s \in S$  in the **original set of sorts**, before adding the “kind”  $[s]$  on top of each connected component  $[s]$  and lifting operators to kinds. I.e., the sufficient completeness for  $\vec{E}$  modulo  $B$  should be required only for terms in the original signature  $\Sigma$  **before** kind-completing it to  $\Sigma^\square$ .

**Example.** For sorts  $Nat$  and  $NzNat$  with  $Nat < NzNat$ , and constructors  $0 : \rightarrow Nat$  and  $s : Nat \rightarrow NzNat$ , the predecessor function  $p : NzNat \rightarrow Nat$  defined by the equation  $p(s(x)) = x$  is sufficiently complete. But the term  $p(0)$  of kind  $[Nat]$  is in normal form, yet is not a constructor term.

## More on Sufficient Completeness (II)

If  $(\Sigma, B, \vec{E})$  has  $\Omega \subseteq \Sigma$  as a constructor subsignature with  $\vec{E}$  terminating modulo  $B$ , we say that the constructors  $\Omega$  are **free modulo  $B$**  in  $(\Sigma, B, \vec{E})$  iff for each sort  $s$  **which is not a kind** and each  $u \in T_{\Omega, s}$  we have  $u = u!_{\vec{E}/B}$ . That is, each  $u \in T_{\Omega, s}$  is in  $\vec{E}, B$ -normal form.

**Example.** **Multisets** of natural numbers, with  $Nat < MSet$ , and constructors  $\emptyset : \rightarrow MSet$  and  $_, _ : MSet \ MSet \rightarrow MSet$  and axioms  $ACU$  for  $_, _$  are free modulo  $ACU$ . But **Sets** of natural numbers, obtained by adding the equation  $n, n = n$ , where  $n$  has sort  $Nat$  are **not** free modulo  $ACU$ . For example, the set  $0, 0, s(0)$  is not in  $\vec{E}, B$ -normal form, since  $(0, 0, s(0))!_{\vec{E}/ACU} = 0, s(0)$ .

# The Canonical Term Algebra

Let  $\text{fmod}(\Sigma, E \cup B)$   $\text{enfm}$  have  $\Sigma$   $B$ -preregular and constructor subsignature  $\Omega \subseteq \Sigma$ ; and let  $(\Sigma, B, \vec{E})$  be sort-decreasing, confluent, terminating and sufficiently complete modulo  $B$  (w.r.t.  $\Omega$ ). Then, the **semantics** of  $\text{fmod}(\Sigma, E \cup B)$   $\text{enfm}$  is defined by its **canonical term algebra**  $\mathbb{C}_{\Sigma/E,B} = (\mathcal{C}_{\Sigma/E,B}, \cdot_{\mathcal{C}_{\Sigma/E,B}})$ , where:

- for each  $s \in S$ ,  $\mathcal{C}_{\Sigma/E,B,s} = \{[u] \in T_{\Omega/B,s} \mid u = u!_{\vec{E}/B}\}$
- For  $a : \rightarrow s$  in  $\Sigma$ ,  $a_{\mathcal{C}_{\Sigma/E,B}} = [a!_{\vec{E}/B}] \in \mathcal{C}_{\Sigma/E,B,s}$ .
- For  $f : s_1 \dots s_n \rightarrow s$  in  $\Sigma$ ,  
 $f_{\mathcal{C}_{\Sigma/E,B}} : \mathcal{C}_{\Sigma/E,B,s_1} \times \dots \times \mathcal{C}_{\Sigma/E,B,s_n} \ni ([t_1], \dots, [t_n]) \mapsto [f(t_1, \dots, t_n)!_{\vec{E}/B}] \in \mathcal{C}_{\Sigma/E,B,s}$ .

Ground confluence and termination imply **Unique Termination**. **Sufficient Completeness** is guaranteed. Sort-decreasingness and  $B$ -preregularity imply **Sort Preservation**.  $\mathbb{C}_{\Sigma/E,B}$  now allows: (i) **axioms**  $B$ , and (ii) constructors that **need not be free** modulo  $B$ .

## Example of Canonical Term Algebra

Consider the following:

- A signature  $\Omega$  of constructors with sorts  $Nat$  and  $Set$ , subsort  $Nat < Set$ , and constructors  $0 : \rightarrow Nat$ ,  $s : Nat \rightarrow Nat$ ,  $\emptyset : \rightarrow Set$  and  $_, _ : Set Set \rightarrow Set$  and axioms  $B = ACU$  for  $\rightarrow, \dots$
- $\Sigma$  adds to  $\Omega$  the function symbol  $+1 : Set \rightarrow Set$ .
- $E = \{(n, n) = n, +1(\emptyset) = \emptyset, +1(n, S) = s(n), +1(S)\}$ , where  $n$  has sort  $Nat$  and  $S$  has sort  $Set$ .

Then, up to the slight change of representation  $n_1, \dots, n_k$  versus  $\{n_1, \dots, n_k\}$ ,  $\mathbb{C}_{\Sigma/E, B}$  is the algebra with sorts  $Nat$ , resp.  $Set$ , interpreted as  $\mathbb{N}$ , resp.  $\mathcal{P}_{fin}(\mathbb{N})$ , set union function, denoted  $\rightarrow, -\mathbb{C}_{\Sigma/E, B}$ , and the function  $+1_{\mathbb{C}_{\Sigma/E, B}}$  increases by 1 each set element.

# Examples of Sufficient Completeness Modulo $B$

For example, consider the reverse function in the list module

```
fmod MY-LIST is protecting NAT .
  sorts NeList List .
  subsorts Nat < NeList < List .
  op _;_ : List List -> List [assoc] .
  op _;_ : NeList NeList -> NeList [assoc ctor] .
  op nil : -> List [ctor] .
  op rev : List -> List .
  eq rev(nil) = nil .
  eq rev(N:Nat ; L:List) = rev(L:List) ; N:Nat .
endfm
```

Are `nil` and `_;` (plus `0` and `s`) really the constructors of this module as claimed?

## Examples of Sufficient Completeness Modulo $B$ (II)

The answer is that they are **not**, as witnessed by:

```
Maude> red rev(7) .  
reduce in MY-LIST : rev(7) .  
rewrites: 0 in 0ms cpu (0ms real) (~ rewrites/second)  
result List: rev(7)
```

The problem is that the above two equations would have been sufficient if we had also declared the `id: nil` attribute for `_`; `_` but do not fully define `rev` if only the `assoc` attribute is used.

In future lectures we shall see how sufficient completeness can be automatically checked under reasonable assumptions.

# Examples of Sufficient Completeness Modulo $B$ (III)

So, suppose we add an extra equation for `rev`

```
fmod MY-LIST is protecting NAT .
  sorts NeList List .
  subsorts Nat < NeList < List .
  op _;_ : List List -> List [assoc] .
  op _;_ : NeList NeList -> NeList [assoc ctor] .
  op nil : -> List [ctor] .
  op rev : List -> List .
  eq rev(nil) = nil .
  eq rev(N:Nat) = N:Nat .
  eq rev(N:Nat ; L:List) = rev(L:List) ; N:Nat .
endfm
```

Is now this module sufficiently complete?

# Examples of Sufficient Completeness Modulo $B$ (IV)

Indeed we now have

```
Maude> red rev(7) .
reduce in MY-LIS
```

But it is still **not** sufficiently complete, since

```
Maude> red nil ; 7 .
reduce in MY-LIST : nil ; 7 .
result List: nil ; 7
```

is **not** a constructor term, since `_;_` is a constructor on `NeList` but a **defined function** on `List`.

# Examples of Sufficient Completeness Modulo $B$ (V)

The really sufficiently complete specification, making the constructors **free** modulo assoc, is

```
fmod MY-LIST is protecting NAT .  sorts NeList List .
  subsorts Nat < NeList < List .
  op _;_ : List List -> List [assoc] .
  op _;_ : NeList NeList -> NeList [assoc ctor] .
  op nil : -> List [ctor] .
  op rev : List -> List .
  eq rev(nil) = nil .
  eq rev(N:Nat) = N:Nat .
  eq rev(N:Nat ; L:List) = rev(L:List) ; N:Nat .
  eq nil ; L:List = L:List .
  eq L:List ; nil = L:List .
endfm
```

```
Maude> red nil ; 7 .
reduce in MY-LIST : nil ; 7 .
result NzNat: 7
```

# Examples of Sufficient Completeness Modulo $B$ (VI)

Sets of natural numbers **do not have free constructors**. The following is another example of an executable equational theory whose constructors are **not free**.

```
fmod NAT/3 is
  sorts Nat .
  op 0 : -> Nat [ctor] .
  op s : Nat -> Nat [ctor] .
  op _+_ : Nat Nat -> Nat .
  vars N M : Nat .
  eq N + 0 = N .
  eq N + s(M) = s(N + M) .
  eq s(s(s(0))) = 0 .
endfm
```
