## CS 498ABD: Algorithms for Big Data

## Probabilistic Counting and Morris Counter <br> Lecture 04 <br> September 1, 2022

## Part I

## Counting Events

## Streaming model

- The input consists of $\boldsymbol{m}$ objects/items/tokens $\boldsymbol{e}_{1}, \boldsymbol{e}_{2}, \ldots, \boldsymbol{e}_{\boldsymbol{m}}$ that are seen one by one by the algorithm.
- The algorithm has "limited" memory say for $\boldsymbol{B}$ tokens where $B<\boldsymbol{m}$ (often $\boldsymbol{B}<\boldsymbol{m}$ ) and hence cannot store all the input
- Want to compute interesting functions over input

## Counting problem

Simplest streaming question: how many events in the stream?

## Counting problem

Simplest streaming question: how many events in the stream?
Obvious: counter that increments on seeing each new item. Requires $\lceil\log \boldsymbol{n}\rceil=\Theta(\log \boldsymbol{n})$ bits to be able to count up to $\boldsymbol{n}$ events.
(We will use $\boldsymbol{n}$ for length of stream for this lecture)

## Counting problem

Simplest streaming question: how many events in the stream?
Obvious: counter that increments on seeing each new item.
Requires $\lceil\log \boldsymbol{n}\rceil=\Theta(\log \boldsymbol{n})$ bits to be able to count up to $\boldsymbol{n}$ events.
(We will use $\boldsymbol{n}$ for length of stream for this lecture)
Question: can we do better?

## Counting problem

Simplest streaming question: how many events in the stream?
Obvious: counter that increments on seeing each new item.
Requires $\lceil\log \boldsymbol{n}\rceil=\Theta(\log \boldsymbol{n})$ bits to be able to count up to $\boldsymbol{n}$ events.
(We will use $\boldsymbol{n}$ for length of stream for this lecture)
Question: can we do better? Not deterministically.

## Counting problem

Simplest streaming question: how many events in the stream?
Obvious: counter that increments on seeing each new item.
Requires $\lceil\log \boldsymbol{n}\rceil=\Theta(\log \boldsymbol{n})$ bits to be able to count up to $\boldsymbol{n}$ events.
(We will use $\boldsymbol{n}$ for length of stream for this lecture)
Question: can we do better? Not deterministically.
Yes, with randomization.
"Counting large numbers of events in small registers" by Rober Morris (Bell Labs), Communications of the ACM (CACM), 1978

## Probabilistic Counting Algorithm

ProbabilisticCounting:
$\boldsymbol{X} \leftarrow 0$
While (a new event arrives)
Toss a biased coin that is heads with probability $1 / 2^{X}$ If (coin turns up heads)

$$
\boldsymbol{X} \leftarrow \boldsymbol{X}+1
$$

endWhile
Output $2^{\boldsymbol{X}}-1$ as the estimate for the length of the stream.

## Probabilistic Counting Algorithm

ProbabilisticCounting:
$\boldsymbol{X} \leftarrow 0$
While (a new event arrives)
Toss a biased coin that is heads with probability $1 / 2^{X}$
If (coin turns up heads)

$$
\boldsymbol{X} \leftarrow \boldsymbol{X}+1
$$

endWhile
Output $2^{\boldsymbol{X}}-1$ as the estimate for the length of the stream.
Intuition: $\boldsymbol{X}$ keeps track of $\log \boldsymbol{n}$ in a probabilistic sense. Hence requires $O(\log \log n)$ bits

## Probabilistic Counting Algorithm

ProbabilisticCounting:
$\boldsymbol{X} \leftarrow 0$
While (a new event arrives)
Toss a biased coin that is heads with probability $1 / 2^{X}$ If (coin turns up heads)

$$
\boldsymbol{X} \leftarrow \boldsymbol{X}+1
$$

endWhile
Output $2^{\boldsymbol{X}}-1$ as the estimate for the length of the stream.
Intuition: $\boldsymbol{X}$ keeps track of $\log \boldsymbol{n}$ in a probabilistic sense. Hence requires $O(\log \log n)$ bits

## Theorem

Let $\boldsymbol{Y}=2^{\boldsymbol{X}}$. Then $\mathrm{E}[\boldsymbol{Y}]-1=\boldsymbol{n}$, the number of events seen.

## $\log n$ vs $\log \log n$

Morris's motivation:

- Had 8 bit registers. Can count only up to $2^{8}=256$ events using deterministic counter. Had many counters for keeping track of different events and using 16 bits ( 2 registers) was infeasible.
- If only $\log \log \boldsymbol{n}$ bits then can count to $2^{2^{8}}=2^{256}$ events! In practice overhead due to error control etc. Morris reports counting up to 130,000 events using 8 bits while controlling error.
See 2 page paper for more details.

## Analysis of Expectation

Induction on $\boldsymbol{n}$. For $\boldsymbol{i} \geq 0$, let $\boldsymbol{X}_{\boldsymbol{i}}$ be the counter value after $\boldsymbol{i}$ events. Let $Y_{i}=2^{X_{i}}$. Both are random variables.

## Analysis of Expectation

Induction on $\boldsymbol{n}$. For $\boldsymbol{i} \geq 0$, let $\boldsymbol{X}_{\boldsymbol{i}}$ be the counter value after $\boldsymbol{i}$ events. Let $Y_{i}=2^{X_{i}}$. Both are random variables.

Base case: $\boldsymbol{n}=0,1$ easy to check: $X_{i}, Y_{i}-1$ deterministically equal to 0,1 .

## Analysis of Expectation

$$
\begin{aligned}
\mathrm{E}\left[\boldsymbol{Y}_{\boldsymbol{n}}\right]= & \mathrm{E}\left[2^{\boldsymbol{X}_{n}}\right]=\sum_{\boldsymbol{j}=0}^{\infty} 2^{\boldsymbol{j}} \operatorname{Pr}\left[\boldsymbol{X}_{\boldsymbol{n}}=\boldsymbol{j}\right] \\
= & \sum_{\boldsymbol{j}=0}^{\infty} 2^{\boldsymbol{j}}\left(\operatorname{Pr}\left[\boldsymbol{X}_{\boldsymbol{n}-1}=\boldsymbol{j}\right] \cdot\left(1-\frac{1}{2^{j}}\right)+\operatorname{Pr}\left[\boldsymbol{X}_{\boldsymbol{n}-1}=\boldsymbol{j}-1\right] \cdot \frac{1}{2^{\boldsymbol{j}-1}}\right) \\
= & \sum_{\boldsymbol{j}=0}^{\infty} 2^{\boldsymbol{j}} \operatorname{Pr}\left[\boldsymbol{X}_{\boldsymbol{n}-1}=\boldsymbol{j}\right] \\
& +\sum_{\boldsymbol{j}=0}^{\infty}\left(2 \operatorname{Pr}\left[\boldsymbol{X}_{\boldsymbol{n}-1}=\boldsymbol{j}-1\right]-\operatorname{Pr}\left[\boldsymbol{X}_{\boldsymbol{n}-1}=\boldsymbol{j}\right]\right) \\
= & \left.\mathrm{E}\left[\boldsymbol{Y}_{\boldsymbol{n}-1}\right]+1 \quad \text { (by applying induction }\right) \\
= & \boldsymbol{n}+1
\end{aligned}
$$

## Jensen's Inequality

## Definition

A real-valued function $f: \mathbb{R} \rightarrow \mathbb{R}$ is convex if $f((\boldsymbol{a}+\boldsymbol{b}) / 2) \leq(\boldsymbol{f}(\boldsymbol{a})+\boldsymbol{f}(\boldsymbol{b})) / 2$ for all $\boldsymbol{a}, \boldsymbol{b}$. Equivalently, $\boldsymbol{f}(\boldsymbol{\lambda} \boldsymbol{a}+(1-\boldsymbol{\lambda}) \boldsymbol{b}) \leq \boldsymbol{\lambda}(\boldsymbol{a})+(1-\boldsymbol{\lambda}) \boldsymbol{f}(\boldsymbol{b})$ for all $\boldsymbol{\lambda} \in[0,1]$.

## Jensen's Inequality

## Definition

A real-valued function $f: \mathbb{R} \rightarrow \mathbb{R}$ is convex if $f((\boldsymbol{a}+\boldsymbol{b}) / 2) \leq(\boldsymbol{f}(\boldsymbol{a})+\boldsymbol{f}(\boldsymbol{b})) / 2$ for all $\boldsymbol{a}, \boldsymbol{b}$. Equivalently, $\boldsymbol{f}(\boldsymbol{\lambda} \boldsymbol{a}+(1-\boldsymbol{\lambda}) \boldsymbol{b}) \leq \boldsymbol{\lambda} \boldsymbol{f}(\boldsymbol{a})+(1-\boldsymbol{\lambda}) \boldsymbol{f}(\boldsymbol{b})$ for all $\boldsymbol{\lambda} \in[0,1]$.

## Theorem (Jensen's inequality)

Let $Z$ be random variable with $\mathrm{E}[Z]<\infty$. If $f$ is convex then $f(E[Z]) \leq E[f(Z)]$.

## Implication for counter size

We have $Y_{\boldsymbol{n}}=2^{X_{n}}$. The function $f(z)=2^{z}$ is convex. Hence

$$
2^{\mathrm{E}\left[\boldsymbol{X}_{n}\right]} \leq \mathrm{E}\left[\boldsymbol{Y}_{\boldsymbol{n}}\right] \leq \boldsymbol{n}+1
$$

which implies

$$
\mathrm{E}\left[\boldsymbol{X}_{\boldsymbol{n}}\right] \leq \log (\boldsymbol{n}+1)
$$

Hence expected number of bits in counter is $\lceil\log \log (\boldsymbol{n}+1))\rceil$.

## Variance calculation

Question: Is the random variable $\boldsymbol{Y}_{\boldsymbol{n}}$ well behaved even though expectation is right? What is its variance? Is it concentrated around expectation?

## Variance calculation

Question: Is the random variable $Y_{\boldsymbol{n}}$ well behaved even though expectation is right? What is its variance? Is it concentrated around expectation?

Lemma
$E\left[Y_{n}^{2}\right]=\frac{3}{2} \boldsymbol{n}^{2}+\frac{3}{2} \boldsymbol{n}+1$ and hence $\operatorname{Var}\left[\boldsymbol{Y}_{\boldsymbol{n}}\right]=\boldsymbol{n}(\boldsymbol{n}-1) / 2$.

## Variance analysis

Analyze $\mathrm{E}\left[Y_{n}^{2}\right]$ via induction.
Base cases: $\boldsymbol{n}=0,1$ are easy to verify since $\boldsymbol{Y}_{\boldsymbol{n}}$ is deterministic.

$$
\begin{aligned}
\boldsymbol{E}\left[\boldsymbol{Y}_{\boldsymbol{n}}^{2}\right]= & \boldsymbol{E}\left[2^{2 \boldsymbol{X}_{n}}\right]=\sum_{j \geq 0} 2^{2 \boldsymbol{j}} \cdot \operatorname{Pr}\left[\boldsymbol{X}_{\boldsymbol{n}}=\boldsymbol{j}\right] \\
= & \sum_{j \geq 0} 2^{2 \boldsymbol{j}} \cdot\left(\operatorname{Pr}\left[\boldsymbol{X}_{\boldsymbol{n}-1}=\boldsymbol{j}\right]\left(1-\frac{1}{2^{j}}\right)+\operatorname{Pr}\left[\boldsymbol{X}_{\boldsymbol{n}-1}=\boldsymbol{j}-1\right] \frac{1}{2^{j-1}}\right) \\
= & \sum_{j \geq 0} 2^{2 j} \cdot \operatorname{Pr}\left[\boldsymbol{X}_{\boldsymbol{n}-1}=\boldsymbol{j}\right] \\
& +\sum_{j \geq 0}\left(-2^{j} \operatorname{Pr}\left[\boldsymbol{X}_{\boldsymbol{n}-1}=\boldsymbol{j}-1\right]+42^{j-1} \operatorname{Pr}\left[\boldsymbol{X}_{\boldsymbol{n}-1}=\boldsymbol{j}-1\right]\right) \\
= & \boldsymbol{E}\left[\boldsymbol{Y}_{\boldsymbol{n}-1}^{2}\right]+3 \boldsymbol{E}\left[\boldsymbol{Y}_{\boldsymbol{n}-1}\right] \\
= & \frac{3}{2}(\boldsymbol{n}-1)^{2}+\frac{3}{2}(\boldsymbol{n}-1)+1+3 \boldsymbol{n}=\frac{3}{2} \boldsymbol{n}^{2}+\frac{3}{2} \boldsymbol{n}+1 . \text { FSA98ABD 2022 }_{12}^{12 / 2}
\end{aligned}
$$

## Error analysis via Chebyshev inequality

We have $E\left[Y_{n}\right]=\boldsymbol{n}$ and $\operatorname{Var}\left(Y_{\boldsymbol{n}}\right)=\boldsymbol{n}(\boldsymbol{n}-1) / 2$ implies
$\sigma_{Y_{n}}=\sqrt{n(n-1) / 2} \leq \boldsymbol{n}$.
Applying Cheybyshev's inequality:

$$
\operatorname{Pr}\left[\left|Y_{n}-\mathrm{E}\left[Y_{n}\right]\right| \geq t n\right] \leq 1 /\left(2 t^{2}\right)
$$

Hence constant factor approximation with constant probability (for instance set $t=1 / 2$ ).

## Error analysis via Chebyshev inequality

We have $E\left[Y_{n}\right]=\boldsymbol{n}$ and $\operatorname{Var}\left(Y_{\boldsymbol{n}}\right)=\boldsymbol{n}(\boldsymbol{n}-1) / 2$ implies
$\sigma_{Y_{n}}=\sqrt{n(n-1) / 2} \leq \boldsymbol{n}$.
Applying Cheybyshev's inequality:

$$
\operatorname{Pr}\left[\left|Y_{n}-\mathrm{E}\left[Y_{n}\right]\right| \geq t n\right] \leq 1 /\left(2 t^{2}\right)
$$

Hence constant factor approximation with constant probability (for instance set $t=1 / 2$ ).
Question: Want estimate to be tighter. For any given $\boldsymbol{\epsilon}>0$ want estimate to have error at most $\boldsymbol{\epsilon} \boldsymbol{n}$ with say constant probability or with probability at least $(1-\boldsymbol{\delta})$ for a given $\delta>0$.

## Part II

## Improving Estimators

## Probabilistic Estimation

Setting: want to compute some real-value function $f$ of a given input I

Probabilistic estimator: a randomized algorithm that given I outputs a random answer $X$ such that $E[X] \simeq f(I)$. Estimator is exact if $\mathrm{E}[\boldsymbol{X}]=\boldsymbol{f}(\boldsymbol{I})$ for all inputs $\boldsymbol{I}$.

Additive approximation: $|\mathrm{E}[X]-f(I)| \leq \epsilon$
Multiplicative approximation: $(1-\epsilon) f(I) \leq \mathrm{E}[X] \leq(1+\epsilon) f(I)$

## Probabilistic Estimation

Setting: want to compute some real-value function $f$ of a given input I

Probabilistic estimator: a randomized algorithm that given I outputs a random answer $X$ such that $\mathrm{E}[X] \simeq f(I)$. Estimator is exact if $\mathrm{E}[\boldsymbol{X}]=\boldsymbol{f}(\boldsymbol{I})$ for all inputs $\boldsymbol{I}$.

Additive approximation: $|\mathrm{E}[X]-f(I)| \leq \epsilon$
Multiplicative approximation: $(1-\epsilon) \boldsymbol{f}(I) \leq \mathrm{E}[\boldsymbol{X}] \leq(1+\boldsymbol{\epsilon}) \boldsymbol{f}(I)$
Question: Estimator only gives expectation. Bound on $\operatorname{Var}[X]$ allows Chebyshev. Sometimes Chernoff applies. How do we improve estimator?

## Variance reduction via averaging

- Run $\boldsymbol{h}$ parallel copies of algorithm with independent randomness
- Let $\boldsymbol{Y}^{(1)}, \boldsymbol{Y}^{(2)}, \ldots, \boldsymbol{Y}^{(\boldsymbol{h})}$ be estimators from the $\boldsymbol{h}$ parallel copies
- Output $Z=\frac{1}{h} \sum_{i=1}^{h} \boldsymbol{Y}^{(i)}$

## Variance reduction via averaging

- Run $\boldsymbol{h}$ parallel copies of algorithm with independent randomness
- Let $\boldsymbol{Y}^{(1)}, \boldsymbol{Y}^{(2)}, \ldots, \boldsymbol{Y}^{(\boldsymbol{h})}$ be estimators from the $\boldsymbol{h}$ parallel copies
- Output $Z=\frac{1}{h} \sum_{i=1}^{h} \boldsymbol{Y}^{(i)}$

Claim: $\mathrm{E}\left[Z_{n}\right]=\boldsymbol{n}$ and $\operatorname{Var}\left(\boldsymbol{Z}_{\boldsymbol{n}}\right)=\frac{1}{h}(\boldsymbol{n}(\boldsymbol{n}-1) / 2)$.

## Variance reduction via averaging

- Run $\boldsymbol{h}$ parallel copies of algorithm with independent randomness
- Let $\boldsymbol{Y}^{(1)}, \boldsymbol{Y}^{(2)}, \ldots, \boldsymbol{Y}^{(\boldsymbol{h})}$ be estimators from the $\boldsymbol{h}$ parallel copies
- Output $Z=\frac{1}{h} \sum_{i=1}^{h} \boldsymbol{Y}^{(i)}$

Claim: $\mathrm{E}\left[Z_{\boldsymbol{n}}\right]=\boldsymbol{n}$ and $\operatorname{Var}\left(\boldsymbol{Z}_{\boldsymbol{n}}\right)=\frac{1}{\boldsymbol{h}}(\boldsymbol{n}(\boldsymbol{n}-1) / 2)$.
Choose $\boldsymbol{h}=\frac{2}{\epsilon^{2}}$. Then applying Cheybyshev's inequality

$$
\operatorname{Pr}\left[\left|Z_{n}-\mathrm{E}\left[Z_{n}\right]\right| \geq \epsilon n\right] \leq 1 / 4
$$

## Variance reduction via averaging

- Run $\boldsymbol{h}$ parallel copies of algorithm with independent randomness
- Let $\boldsymbol{Y}^{(1)}, \boldsymbol{Y}^{(2)}, \ldots, \boldsymbol{Y}^{(\boldsymbol{h})}$ be estimators from the $\boldsymbol{h}$ parallel copies
- Output $Z=\frac{1}{h} \sum_{i=1}^{h} \boldsymbol{Y}^{(i)}$

Claim: $\mathrm{E}\left[Z_{\boldsymbol{n}}\right]=\boldsymbol{n}$ and $\operatorname{Var}\left(\boldsymbol{Z}_{\boldsymbol{n}}\right)=\frac{1}{\boldsymbol{h}}(\boldsymbol{n}(\boldsymbol{n}-1) / 2)$.
Choose $\boldsymbol{h}=\frac{2}{\epsilon^{2}}$. Then applying Cheybyshev's inequality

$$
\operatorname{Pr}\left[\left|Z_{n}-\mathrm{E}\left[Z_{n}\right]\right| \geq \epsilon n\right] \leq 1 / 4
$$

To run $\boldsymbol{h}$ copies need $\boldsymbol{O}\left(\frac{1}{\epsilon^{2}} \log \log n\right)$ bits for the counters.

## Error reduction via median trick

We have:

$$
\operatorname{Pr}\left[\left|Z_{\boldsymbol{n}}-\mathrm{E}\left[Z_{\boldsymbol{n}}\right]\right| \geq \boldsymbol{\epsilon} \boldsymbol{n}\right] \leq 1 / 4
$$

Want:

$$
\operatorname{Pr}\left[\left|Z_{n}-\mathrm{E}\left[Z_{n}\right]\right| \geq \epsilon n\right] \leq \delta
$$

for some given parameter $\boldsymbol{\delta}$.

## Error reduction via median trick

We have:

$$
\operatorname{Pr}\left[\left|Z_{\boldsymbol{n}}-\mathrm{E}\left[Z_{\boldsymbol{n}}\right]\right| \geq \boldsymbol{\epsilon}\right] \leq 1 / 4
$$

Want:

$$
\operatorname{Pr}\left[\left|Z_{n}-\mathrm{E}\left[Z_{n}\right]\right| \geq \epsilon \boldsymbol{n}\right] \leq \boldsymbol{\delta}
$$

for some given parameter $\boldsymbol{\delta}$.
Can set $\boldsymbol{h}=\frac{1}{2 \epsilon^{2} \boldsymbol{\delta}}$ and apply Chebyshev. Better dependence on $\boldsymbol{\delta}$ ?

## Error reduction via median trick

We have:

$$
\operatorname{Pr}\left[\left|Z_{n}-\mathrm{E}\left[Z_{n}\right]\right| \geq \epsilon \boldsymbol{n}\right] \leq 1 / 4
$$

Want:

$$
\operatorname{Pr}\left[\left|Z_{n}-\mathrm{E}\left[Z_{n}\right]\right| \geq \epsilon n\right] \leq \delta
$$

for some given parameter $\boldsymbol{\delta}$.
Can set $\boldsymbol{h}=\frac{1}{2 \epsilon^{2} \boldsymbol{\delta}}$ and apply Chebyshev. Better dependence on $\boldsymbol{\delta}$ ?
Idea: Repeat independently $\boldsymbol{c} \log (1 / \boldsymbol{\delta})$ times for some constant $\boldsymbol{c}$. We know that with probability $(1-\boldsymbol{\delta})$ one of the counters will be $\boldsymbol{\epsilon} \boldsymbol{n}$ close to $n$. Why?

## Error reduction via median trick

We have:

$$
\operatorname{Pr}\left[\left|Z_{n}-\mathrm{E}\left[Z_{n}\right]\right| \geq \epsilon \boldsymbol{n}\right] \leq 1 / 4
$$

Want:

$$
\operatorname{Pr}\left[\left|Z_{n}-\mathrm{E}\left[Z_{n}\right]\right| \geq \epsilon n\right] \leq \delta
$$

for some given parameter $\boldsymbol{\delta}$.
Can set $\boldsymbol{h}=\frac{1}{2 \epsilon^{2} \boldsymbol{\delta}}$ and apply Chebyshev. Better dependence on $\boldsymbol{\delta}$ ?
Idea: Repeat independently $\boldsymbol{c} \log (1 / \boldsymbol{\delta})$ times for some constant $\boldsymbol{c}$. We know that with probability $(1-\boldsymbol{\delta})$ one of the counters will be $\boldsymbol{\epsilon} \boldsymbol{n}$ close to $n$. Why? Which one should we pick?

## Error reduction via median trick

We have:

$$
\operatorname{Pr}\left[\left|Z_{n}-\mathrm{E}\left[Z_{n}\right]\right| \geq \epsilon n\right] \leq 1 / 4
$$

Want:

$$
\operatorname{Pr}\left[\left|Z_{n}-\mathrm{E}\left[Z_{n}\right]\right| \geq \epsilon n\right] \leq \delta
$$

for some given parameter $\boldsymbol{\delta}$.
Can set $\boldsymbol{h}=\frac{1}{2 \epsilon^{2} \boldsymbol{\delta}}$ and apply Chebyshev. Better dependence on $\boldsymbol{\delta}$ ?
Idea: Repeat independently $\boldsymbol{c} \log (1 / \boldsymbol{\delta})$ times for some constant $\boldsymbol{c}$. We know that with probability $(1-\boldsymbol{\delta})$ one of the counters will be $\boldsymbol{\epsilon} \boldsymbol{n}$ close to $n$. Why? Which one should we pick?

Algorithm: Output median of $\boldsymbol{Z}^{(1)}, \boldsymbol{Z}^{(2)}, \ldots, \boldsymbol{Z}^{(\ell)}$.

## Error reduction via median trick

Let $Z^{\prime}$ be median of the $\ell=\boldsymbol{c} \log (1 / \delta)$ independent estimators.
Lemma
$\operatorname{Pr}\left[\left|Z^{\prime}-\boldsymbol{n}\right| \geq \boldsymbol{\epsilon}\right] \leq \boldsymbol{\delta}$.

## Error reduction via median trick

Let $Z^{\prime}$ be median of the $\ell=\boldsymbol{c} \log (1 / \delta)$ independent estimators.
Lemma
$\operatorname{Pr}\left[\left|Z^{\prime}-\boldsymbol{n}\right| \geq \boldsymbol{\epsilon}\right] \leq \boldsymbol{\delta}$.

- Let $\boldsymbol{A}_{\boldsymbol{i}}$ be event that estimate $\boldsymbol{Z}^{(\boldsymbol{i})}$ is bad: that is, $\left|\boldsymbol{Z}^{(\boldsymbol{i})}-\boldsymbol{n}\right|>\boldsymbol{\epsilon} \boldsymbol{n} . \operatorname{Pr}\left[\boldsymbol{A}_{\boldsymbol{i}}\right]<1 / 4$. Hence expected number of bad estimates is $\ell / 4$.

## Error reduction via median trick

Let $Z^{\prime}$ be median of the $\ell=\boldsymbol{c} \log (1 / \delta)$ independent estimators.
Lemma
$\operatorname{Pr}\left[\left|Z^{\prime}-\boldsymbol{n}\right| \geq \boldsymbol{\epsilon}\right] \leq \boldsymbol{\delta}$.

- Let $\boldsymbol{A}_{\boldsymbol{i}}$ be event that estimate $\boldsymbol{Z}^{(\boldsymbol{i})}$ is bad: that is, $\left|\boldsymbol{Z}^{(\boldsymbol{i})}-\boldsymbol{n}\right|>\boldsymbol{\epsilon} \boldsymbol{n} . \operatorname{Pr}\left[\boldsymbol{A}_{\boldsymbol{i}}\right]<1 / 4$. Hence expected number of bad estimates is $\ell / 4$.
- For median estimate to be bad, more than half of $\boldsymbol{A}_{\boldsymbol{i}}$ 's have to be bad.

## Error reduction via median trick

Let $Z^{\prime}$ be median of the $\ell=\boldsymbol{c} \log (1 / \delta)$ independent estimators.

## Lemma

$\operatorname{Pr}\left[\left|Z^{\prime}-\boldsymbol{n}\right| \geq \epsilon \boldsymbol{n}\right] \leq \boldsymbol{\delta}$

- Let $\boldsymbol{A}_{\boldsymbol{i}}$ be event that estimate $\boldsymbol{Z}^{(\boldsymbol{i})}$ is bad: that is, $\left|\boldsymbol{Z}^{(\boldsymbol{i})}-\boldsymbol{n}\right|>\boldsymbol{\epsilon} \boldsymbol{n} . \operatorname{Pr}\left[\boldsymbol{A}_{\boldsymbol{i}}\right]<1 / 4$. Hence expected number of bad estimates is $\ell / 4$.
- For median estimate to be bad, more than half of $\boldsymbol{A}_{\boldsymbol{i}}$ 's have to be bad.
- Using Chernoff bounds: probability of bad median is at most $2^{-c^{\prime} \ell}$ for some constant $c^{\prime}$.

## Summarizing

Using variance reduction and median trick: with $\boldsymbol{O}\left(\frac{1}{\epsilon^{2}} \log (1 / \boldsymbol{\delta}) \log \log \boldsymbol{n}\right)$ bits one can maintain a $(1-\boldsymbol{\epsilon})$-factor estimate of the number of events with probability $(1-\boldsymbol{\delta})$. This is a generic scheme that we will repeatedly use.

For counter one can do (much) better by changing algorithm and better analysis. See homework and references in notes.
