## CS 498ABD: Algorithms for Big Data

 Limited independence andHashing
Lecture $05 / 06$
September 6 and 8,2022

## Pseudorandomness

Randomized algorithms rely on independent random bits
Psuedorandomness: when can we avoid or limit number of random bits?

- Motivated by fundamental theoretical questions and applications
- Applications: hashing, cryptography, streaming, simulations, derandomization, ...
- A large topic in TCS with many connections to mathematics.

This course: need $t$-wise independent variables and hashing

## Part I

## Pairwise and $t$-wise independent random variables

## Pairwise independent random variables

## Definition

Discrete random variables $X_{1}, X_{2}, \ldots, X_{n}$ from a range $B$ are independent if for all $b_{1}, b_{2}, \ldots, b_{n} \in B$

$$
\operatorname{Pr}\left[\boldsymbol{X}_{1}=\boldsymbol{b}_{1}, \boldsymbol{X}_{2}=\boldsymbol{b}_{2}, \ldots, \boldsymbol{X}_{\boldsymbol{n}}=\boldsymbol{b}_{\boldsymbol{n}}\right]=\prod_{\boldsymbol{i}=1}^{n} \operatorname{Pr}\left[\boldsymbol{X}_{\boldsymbol{i}}=\boldsymbol{b}_{\boldsymbol{i}}\right]
$$

Uniformly distributed if $\operatorname{Pr}\left[\boldsymbol{X}_{\boldsymbol{i}}=\boldsymbol{b}\right]=1 /|\boldsymbol{B}|$ for all $\boldsymbol{i}, \boldsymbol{b} \in \boldsymbol{B}$.

## Pairwise independent random variables

## Definition

Discrete random variables $X_{1}, X_{2}, \ldots, X_{\boldsymbol{n}}$ from a range $B$ are independent if for all $\boldsymbol{b}_{1}, \boldsymbol{b}_{2}, \ldots, \boldsymbol{b}_{\boldsymbol{n}} \in B$

$$
\operatorname{Pr}\left[\boldsymbol{X}_{1}=\boldsymbol{b}_{1}, \boldsymbol{X}_{2}=\boldsymbol{b}_{2}, \ldots, \boldsymbol{X}_{\boldsymbol{n}}=\boldsymbol{b}_{\boldsymbol{n}}\right]=\prod_{\boldsymbol{i}=1}^{\boldsymbol{n}} \operatorname{Pr}\left[\boldsymbol{X}_{\boldsymbol{i}}=\boldsymbol{b}_{\boldsymbol{i}}\right]
$$

Uniformly distributed if $\operatorname{Pr}\left[\boldsymbol{X}_{\boldsymbol{i}}=\boldsymbol{b}\right]=1 /|\boldsymbol{B}|$ for all $\boldsymbol{i}, \boldsymbol{b} \in \boldsymbol{B}$.

## Definition

Random variables $X_{1}, X_{2}, \ldots, X_{\boldsymbol{n}}$ from a range $B$ are pairwise independent if for all $1 \leq i<j \leq n$ and for all $\boldsymbol{b}, \boldsymbol{b}^{\prime} \in B$,

$$
\operatorname{Pr}\left[\boldsymbol{X}_{\boldsymbol{i}}=\boldsymbol{b}, \boldsymbol{X}_{\boldsymbol{j}}=\boldsymbol{b}^{\prime}\right]=\operatorname{Pr}\left[\boldsymbol{X}_{\boldsymbol{i}}=\boldsymbol{b}\right] \cdot \operatorname{Pr}\left[\boldsymbol{X}_{\boldsymbol{j}}=\boldsymbol{b}^{\prime}\right]
$$

## Pairwise independent random variables

## Definition

Random variables $X_{1}, X_{2}, \ldots, X_{n}$ from a range $B$ are pairwise independent if for all $1 \leq \boldsymbol{i}<\boldsymbol{j} \leq \boldsymbol{n}$ and for all $\boldsymbol{b}, \boldsymbol{b}^{\prime} \in B$,

$$
\operatorname{Pr}\left[\boldsymbol{X}_{\boldsymbol{i}}=\boldsymbol{b}, \boldsymbol{X}_{\boldsymbol{j}}=\boldsymbol{b}^{\prime}\right]=\operatorname{Pr}\left[\boldsymbol{X}_{\boldsymbol{i}}=\boldsymbol{b}\right] \cdot \operatorname{Pr}\left[\boldsymbol{X}_{\boldsymbol{j}}=\boldsymbol{b}^{\prime}\right] .
$$

If $X_{1}, X_{2}, \ldots, X_{n}$ are independent than they are pairwise independent but converse is not necessarily true

## Pairwise independent random variables

## Definition

Random variables $X_{1}, X_{2}, \ldots, X_{n}$ from a range $B$ are pairwise independent if for all $1 \leq \boldsymbol{i}<\boldsymbol{j} \leq \boldsymbol{n}$ and for all $\boldsymbol{b}, \boldsymbol{b}^{\prime} \in B$,

$$
\operatorname{Pr}\left[\boldsymbol{X}_{\boldsymbol{i}}=\boldsymbol{b}, \boldsymbol{X}_{\boldsymbol{j}}=\boldsymbol{b}^{\prime}\right]=\operatorname{Pr}\left[\boldsymbol{X}_{\boldsymbol{i}}=\boldsymbol{b}\right] \cdot \operatorname{Pr}\left[\boldsymbol{X}_{\boldsymbol{j}}=\boldsymbol{b}^{\prime}\right] .
$$

If $X_{1}, X_{2}, \ldots, X_{n}$ are independent than they are pairwise independent but converse is not necessarily true

Example: $\boldsymbol{X}_{1}, \boldsymbol{X}_{2}$ are independent bits (variables from $\{0,1\}$ ) and $X_{3}=X_{1} \oplus X_{2} . X_{1}, X_{2}, X_{3}$ are pairwise independent but not independent.

## $t$-wise independence

Generalizing pairwise independence:

## Definition

Random variables $X_{1}, X_{2}, \ldots, X_{\boldsymbol{n}}$ from a range $B$ are $\boldsymbol{t}$-wise independent for integer $t>1 X_{i_{1}}, X_{i_{2}}, \ldots, X_{i_{t}}$ are independent for any $i_{1} \neq i_{2} \neq \ldots \neq i_{t} \in\{1,2, \ldots, n\}$.

As $t$ increases the variables become more and more independent. If $\boldsymbol{t}=\boldsymbol{n}$ the variables are independent.

## Motivation for pairwise/t-wise independence from streaming

Want $n$ uniformly distr random variables $X_{1}, X_{2}, \ldots, X_{n}$, say bits But cannot store $\boldsymbol{n}$ bits because $\boldsymbol{n}$ is too large.

Achievable:

- storage of $O(\log n)$ random bits
- given $\boldsymbol{i}$ where $1 \leq \boldsymbol{i} \leq \boldsymbol{n}$ can generate $\boldsymbol{X}_{\boldsymbol{i}}$ in $\boldsymbol{O}(\log n)$ time
- $X_{1}, X_{2}, \ldots, X_{n}$ are pairwise independent and uniform
- Hence, with small storage, can generate $\boldsymbol{n}$ random variables "on the fly". In several applications, pairwise independence (or generalizations) suffice

## Generating pairwise independent bits

Assume for simplicity $\boldsymbol{n}=2^{\boldsymbol{k}}-1$ (otherwise consider nearest power of 2). Hence $\boldsymbol{k}=\boldsymbol{O}(\log \boldsymbol{n})$

- Let $Y_{1}, Y_{2}, \ldots, Y_{\boldsymbol{k}}$ be independent bits
- For any $S \subset\{1,2, \ldots, k\}, S \neq \emptyset$, define $X_{S}=\oplus_{i \in S} Y_{i}$
- $2^{k}-1$ random variables $X_{S}$

## Generating pairwise independent bits

Assume for simplicity $\boldsymbol{n}=2^{k}-1$ (otherwise consider nearest power of 2). Hence $\boldsymbol{k}=\boldsymbol{O}(\log \boldsymbol{n})$

- Let $Y_{1}, Y_{2}, \ldots, Y_{k}$ be independent bits
- For any $S \subset\{1,2, \ldots, k\}, S \neq \emptyset$, define $X_{S}=\oplus_{i \in S} Y_{i}$
- $2^{k}-1$ random variables $X_{S}$

Claim: If $S \neq T$ then $X_{S}$ and $X_{T}$ are independent

## Generating pairwise independent bits

Assume for simplicity $\boldsymbol{n}=2^{k}-1$ (otherwise consider nearest power of 2). Hence $\boldsymbol{k}=\boldsymbol{O}(\log \boldsymbol{n})$

- Let $Y_{1}, Y_{2}, \ldots, Y_{k}$ be independent bits
- For any $S \subset\{1,2, \ldots, k\}, S \neq \emptyset$, define $X_{S}=\oplus_{i \in S} Y_{i}$
- $2^{k}-1$ random variables $X_{S}$

Claim: If $S \neq T$ then $X_{S}$ and $X_{T}$ are independent

## Proof.

$X_{S}$ and $X_{T}$ are both uniformaly distributed over $\{0,1\}$. Suppose $S-T \neq \emptyset$. Even knowing all outcomes of variables in $T$ the variables in $S-\boldsymbol{T}$ are independent and hence $\operatorname{Pr}\left[\boldsymbol{X}_{\boldsymbol{S}}=0 \mid \boldsymbol{T}\right]=1 / 2$ and hence $\boldsymbol{X}_{\boldsymbol{S}}$ is independent of $\boldsymbol{X}_{\boldsymbol{T}}$. If $S \subset T$ then apply same argument to $T-S$.

## Pairwise independent variables with larger range

Suppose we want $\boldsymbol{n}$ pairwise independent random variables in range $\{0,1,2, \ldots, \boldsymbol{m}-1\}$ where $\boldsymbol{m}=2^{k}-1$ for some $\boldsymbol{k}$

## Pairwise independent variables with larger <br> range

Suppose we want $n$ pairwise independent random variables in range $\{0,1,2, \ldots, \boldsymbol{m}-1\}$ where $\boldsymbol{m}=2^{k}-1$ for some $\boldsymbol{k}$

- Now each $X_{i}$ needs to be a $\log m$ bit string
- Use preceding construction for each bit independently
- Requires $O(\log m \log n)$ bits total
- Can in fact do $O(\log n+\log m)$ bits

## Using prime numbers and fields

Assume $\boldsymbol{n}=\boldsymbol{m}=\boldsymbol{p}$ where $\boldsymbol{p}$ is a prime number

Want $p$ pairwise random variables distributed uniformly in $\mathbb{Z}_{\boldsymbol{p}}=\{0,1,2, \ldots, \boldsymbol{p}-1\}$

## Using prime numbers and fields

Assume $\boldsymbol{n}=\boldsymbol{m}=\boldsymbol{p}$ where $\boldsymbol{p}$ is a prime number
Want $\boldsymbol{p}$ pairwise random variables distributed uniformly in $\mathbb{Z}_{\boldsymbol{p}}=\{0,1,2, \ldots, \boldsymbol{p}-1\}$

- Choose $\boldsymbol{a}, \boldsymbol{b} \in\{0,1,2, \ldots, \boldsymbol{p}-1\}$ uniformly and independently at random. Requires $2\lceil\log p\rceil$ random bits
- For $0 \leq \boldsymbol{i} \leq \boldsymbol{p}-1$ set $\boldsymbol{X}_{\boldsymbol{i}}=\boldsymbol{a i}+\boldsymbol{b} \bmod \boldsymbol{p}$
- Note that one needs to store only $\boldsymbol{a}, \boldsymbol{b}, \boldsymbol{p}$ and can generate $\boldsymbol{X}_{\boldsymbol{i}}$ efficiently on the fly from $\boldsymbol{i}$

## Using prime numbers and fields

Assume $\boldsymbol{n}=\boldsymbol{m}=\boldsymbol{p}$ where $\boldsymbol{p}$ is a prime number
Want $\boldsymbol{p}$ pairwise random variables distributed uniformly in
$\mathbb{Z}_{\boldsymbol{p}}=\{0,1,2, \ldots, \boldsymbol{p}-1\}$

- Choose $\boldsymbol{a}, \boldsymbol{b} \in\{0,1,2, \ldots, \boldsymbol{p}-1\}$ uniformly and independently at random. Requires $2\lceil\log p\rceil$ random bits
- For $0 \leq \boldsymbol{i} \leq \boldsymbol{p}-1$ set $\boldsymbol{X}_{\boldsymbol{i}}=\boldsymbol{a i}+\boldsymbol{b} \bmod \boldsymbol{p}$
- Note that one needs to store only $\boldsymbol{a}, \boldsymbol{b}, \boldsymbol{p}$ and can generate $\boldsymbol{X}_{\boldsymbol{i}}$ efficiently on the fly from $i$
Exercise: Prove that each $\boldsymbol{X}_{\boldsymbol{i}}$ is uniformly distributed in $\mathbb{Z}_{\boldsymbol{p}}$. Claim: For $\boldsymbol{i} \neq \boldsymbol{j}, \boldsymbol{X}_{\boldsymbol{i}}$ and $\boldsymbol{X}_{\boldsymbol{j}}$ are independent.

## Using prime numbers and fields

Claim: For $\boldsymbol{i} \neq \boldsymbol{j}, \boldsymbol{X}_{\boldsymbol{i}}$ and $\boldsymbol{X}_{\boldsymbol{j}}$ are independent.
Some math required:

- $\mathbb{Z}_{\boldsymbol{p}}$ is a field for any prime $\boldsymbol{p}$. That is $\{0,1,2, \ldots, \boldsymbol{p}-1\}$ forms a commutative group under addition $\bmod \boldsymbol{p}$ (easy). And more importantly $\{1,2, \ldots, p-1\}$ forms a commutative group under multiplication.

## Some math required...

## Lemma (LemmaUnique)

Let $\boldsymbol{p}$ be a prime number,
$\boldsymbol{x}$ : an integer number in $\{1, \ldots, \boldsymbol{p}-1\}$.
$\Longrightarrow$ There exists a unique $y$ s.t. $x y=1 \bmod p$.
In other words: For every element there is a unique inverse.
$\Longrightarrow \mathbb{Z}_{\boldsymbol{p}}=\{0,1, \ldots, \boldsymbol{p}-1\}$ when working modulo $\boldsymbol{p}$ is a field.

## Proof of LemmaUnique

## Claim

Let $p$ be a prime number. For any $x, y, z \in\{1, \ldots, p-1\}$ s.t. $y \neq z$, we have that $x y \bmod p \neq x z \bmod p$.

## Proof.

Assume for the sake of contradiction $x y \bmod p=x z \bmod p$.

$$
\begin{aligned}
& x(y-z)=0 \quad \bmod p \\
& \Longrightarrow \quad p \text { divides } x(y-z) \\
& \Longrightarrow \quad p \text { divides } y-z \\
& \Longrightarrow \quad y-z=0 \\
& \Longrightarrow \quad y=z
\end{aligned}
$$

And that is a contradiction.

## Proof of LemmaUnique

## Lemma (LemmaUnique)

Let $\boldsymbol{p}$ be a prime number, $x$ : an integer number in $\{1, \ldots, p-1\}$.
$\Longrightarrow$ There exists a unique $y$ s.t. $x y=1 \bmod p$.

## Proof.

By the above claim if $x y=1 \bmod p$ and $x z=1 \bmod p$ then $\boldsymbol{y}=\boldsymbol{z}$. Hence uniqueness follows.

## Proof of LemmaUnique

## Lemma (LemmaUnique)

Let $\boldsymbol{p}$ be a prime number, $\boldsymbol{x}$ : an integer number in $\{1, \ldots, \boldsymbol{p}-1\}$.
$\Longrightarrow$ There exists a unique $y$ s.t. $x y=1 \bmod p$.

## Proof.

By the above claim if $x y=1 \bmod p$ and $x z=1 \bmod p$ then $\boldsymbol{y}=\boldsymbol{z}$. Hence uniqueness follows.

Existence. For any $x \in\{1, \ldots, p-1\}$ we have that $\{x * 1 \bmod p, x * 2 \bmod p, \ldots, x *(p-1) \bmod p\}=$ $\{1,2, \ldots, p-1\}$.
$\Longrightarrow$ There exists a number $y \in\{1, \ldots, p-1\}$ such that $x y=1$ $\bmod p$.

## Proof of pairwise independence

## Lemma

If $\boldsymbol{i} \neq \boldsymbol{j}$ then for each
$(\boldsymbol{r}, \boldsymbol{s}) \in \mathbb{Z}_{\boldsymbol{p}} \times \mathbb{Z}_{\boldsymbol{p}}$ there is exactly one pair $(\boldsymbol{a}, \boldsymbol{b}) \in \mathbb{Z}_{\boldsymbol{p}} \times \mathbb{Z}_{\boldsymbol{p}}$ such that $\boldsymbol{a i}+\boldsymbol{b} \bmod p=r$ and $a j+b \bmod p=s$

## Proof.

Solve the two equations:

$$
a i+b=r \quad \bmod p \quad \text { and } \quad a j+b=s \quad \bmod p
$$

We get $\boldsymbol{a}=\frac{r-\boldsymbol{s}}{i-j} \bmod \boldsymbol{p}$ and $\boldsymbol{b}=\boldsymbol{r}-\boldsymbol{a x} \bmod \boldsymbol{p}$.
One-to-one correspondence between $(\boldsymbol{a}, \boldsymbol{b})$ and $(\boldsymbol{r}, \boldsymbol{s})$

## Proof of pairwise independence

## Lemma

If $\boldsymbol{i} \neq \boldsymbol{j}$ then for each
$(\boldsymbol{r}, \boldsymbol{s}) \in \mathbb{Z}_{\boldsymbol{p}} \times \mathbb{Z}_{\boldsymbol{p}}$ there is exactly one pair $(\boldsymbol{a}, \boldsymbol{b}) \in \mathbb{Z}_{\boldsymbol{p}} \times \mathbb{Z}_{\boldsymbol{p}}$ such that $\boldsymbol{a i}+\boldsymbol{b} \bmod p=r$ and $a j+b \bmod p=s$

## Proof.

Solve the two equations:

$$
a i+b=r \quad \bmod p \quad \text { and } \quad a j+b=s \quad \bmod p
$$

We get $\boldsymbol{a}=\frac{\boldsymbol{r}-\boldsymbol{s}}{\boldsymbol{i}-\boldsymbol{j}} \bmod \boldsymbol{p}$ and $\boldsymbol{b}=\boldsymbol{r}-\boldsymbol{a x} \bmod \boldsymbol{p}$.
One-to-one correspondence between $(\boldsymbol{a}, \boldsymbol{b})$ and $(\boldsymbol{r}, \boldsymbol{s})$ $\Rightarrow$ if $(\boldsymbol{a}, \boldsymbol{b})$ is uniformly at random from $\mathbb{Z}_{\boldsymbol{p}} \times \mathbb{Z}_{\boldsymbol{p}}$ then $(r, s)$ is uniformly at random from $\mathbb{Z}_{\boldsymbol{p}} \times \mathbb{Z}_{\boldsymbol{p}} . \boldsymbol{X}_{\boldsymbol{i}}, \boldsymbol{X}_{\boldsymbol{j}}$ independent.

## Pairwise independence for $n, m$ powers of 2

We saw how to create $\boldsymbol{n}$ pairwise independent random variables when $\boldsymbol{n}=\boldsymbol{m}=\boldsymbol{p}$ where $\boldsymbol{p}$ is a prime number. We want $\boldsymbol{n}, \boldsymbol{m}$ arbitrary. Easy to assume $\boldsymbol{n}$ is power of 2 (discard the unnecessary rvs) but harder if $\boldsymbol{m}$ is not power of 2 . Here we only consider powers of 2 .
$\boldsymbol{n}>\boldsymbol{m}$ is the more difficult case and also relevant.
The following is a fundamental theorem on finite fields.

## Theorem

Every finite field $\mathbb{F}$ has order $\boldsymbol{p}^{\boldsymbol{k}}$ for some prime $\boldsymbol{p}$ and some integer $k \geq 1$. For every prime $\boldsymbol{p}$ and integer $k \geq 1$ there is a finite field $\mathbb{F}$ of order $\boldsymbol{p}^{k}$ and is unique up to isomorphism.

We will assume $\boldsymbol{n}$ and $\boldsymbol{m}$ are powers of 2 . From above can assume we have a field $\mathbb{F}$ of size $\boldsymbol{n}=2^{k}$.

## Pairwise independence for $n, m$ powers of 2

We have a field $\mathbb{F}$ of size $\boldsymbol{n}=2^{k}$.
Generate $n$ pairwise independent random variables from $[n]$ to $[\boldsymbol{n}]$ by picking random $\boldsymbol{a}, \boldsymbol{b} \in \mathbb{F}$ and setting $\boldsymbol{X}_{\boldsymbol{i}}=\boldsymbol{a i}+\boldsymbol{b}$ (operations in $\mathbb{F}$ ). From previous proof (we only used that $\mathbb{Z}_{\boldsymbol{p}}$ is a field) $\boldsymbol{X}_{\boldsymbol{i}}$ are pairwise independent.

Now $\boldsymbol{X}_{\boldsymbol{i}} \in[\boldsymbol{n}]$. Truncate $\boldsymbol{X}_{\boldsymbol{i}}$ to [ $\left.\boldsymbol{m}\right]$ by dropping the most significant $\log n-\log m$ bits. Resulting variables are still pairwise independent (both $\boldsymbol{n}, \boldsymbol{m}$ being powers of 2 useful here).

Need to only store $\boldsymbol{a}, \boldsymbol{b}, \boldsymbol{n}$ and can generate $\boldsymbol{X}_{\boldsymbol{i}}=\boldsymbol{a i}+\boldsymbol{b}$. Skipping details on computational aspects of $\mathbb{F}$ which are closely tied to the proof of the theorem on fields.

## $t$-wise independence

Generalizing pairwise independence:

## Definition

Random variables $X_{1}, X_{2}, \ldots, X_{n}$ from a range $B$ are $t$-wise independent for integer $t>1 X_{i_{1}}, X_{i_{2}}, \ldots, X_{i_{t}}$ are independent for any $i_{1} \neq i_{2} \neq \ldots \neq i_{t} \in\{1,2, \ldots, n\}$.

As $t$ increases the variables become more and more independent. If $\boldsymbol{t}=\boldsymbol{n}$ the variables are independent.

Fact: For any $\boldsymbol{n}, \boldsymbol{m}$ one can create $\boldsymbol{n}$ random $\boldsymbol{t}$-wise independent random variables from the range $[m]$ using $O(t(\log n+\log m))$ true random bits. Can store only bits and generate the variables on the fly in $O(t$ polylog $(\boldsymbol{m}+\boldsymbol{n}))$ time.

## $t$-wise independence

Construction using polynomials

- Let $\mathbb{F}$ be a field
- Pick $t$ random (with replacement) numbers from $\mathbb{F}$ :
$a_{0}, a_{1}, \ldots, a_{t-1}$
- For each $i \in[|\mathbb{F}|]$ set $X_{i}=a_{0}+a_{1} i+\boldsymbol{a}_{2} i^{2}+\ldots+\boldsymbol{a}_{\boldsymbol{t - 1}} \boldsymbol{i}^{\boldsymbol{t - 1}}$

## Pairwise Independence and Chebyshev's Inequality

## Chebyshev's Inequality

For $a \geq 0, \operatorname{Pr}[|\boldsymbol{X}-\mathrm{E}[\boldsymbol{X}]| \geq a] \leq \frac{\operatorname{Var}(\boldsymbol{X})}{\boldsymbol{a}^{2}}$ equivalently for any $\boldsymbol{t}>0, \operatorname{Pr}\left[|\boldsymbol{X}-\mathrm{E}[\boldsymbol{X}]| \geq \boldsymbol{t} \sigma_{\boldsymbol{x}}\right] \leq \frac{1}{\boldsymbol{t}^{2}}$ where $\sigma_{\boldsymbol{X}}=\sqrt{\operatorname{Var}(\boldsymbol{X})}$ is the standard deviation of $\boldsymbol{X}$.

Suppose $\boldsymbol{X}=\boldsymbol{X}_{1}+\boldsymbol{X}_{2}+\ldots+\boldsymbol{X}_{\boldsymbol{n}}$.
If $X_{1}, X_{2}, \ldots, X_{\boldsymbol{n}}$ are independent then $\operatorname{Var}(\boldsymbol{X})=\sum_{i} \operatorname{Var}\left(\boldsymbol{X}_{\boldsymbol{i}}\right)$.
Recall application to random walk on line

## Pairwise Independence and Chebyshev's Inequality

## Chebyshev's Inequality

For $a \geq 0, \operatorname{Pr}[|\boldsymbol{X}-\mathrm{E}[\boldsymbol{X}]| \geq a] \leq \frac{\operatorname{Var}(\boldsymbol{X})}{\boldsymbol{a}^{2}}$ equivalently for any $\boldsymbol{t}>0, \operatorname{Pr}\left[|\boldsymbol{X}-\mathrm{E}[\boldsymbol{X}]| \geq \boldsymbol{t} \sigma_{\boldsymbol{x}}\right] \leq \frac{1}{\boldsymbol{t}^{2}}$ where $\sigma_{\boldsymbol{X}}=\sqrt{\operatorname{Var}(\boldsymbol{X})}$ is the standard deviation of $\boldsymbol{X}$.

Suppose $\boldsymbol{X}=\boldsymbol{X}_{1}+\boldsymbol{X}_{2}+\ldots+\boldsymbol{X}_{\boldsymbol{n}}$.
If $X_{1}, X_{2}, \ldots, X_{\boldsymbol{n}}$ are independent then $\operatorname{Var}(\boldsymbol{X})=\sum_{i} \operatorname{Var}\left(\boldsymbol{X}_{\boldsymbol{i}}\right)$. Recall application to random walk on line

## Lemma

Suppose $\boldsymbol{X}=\sum_{i} \boldsymbol{X}_{\boldsymbol{i}}$ and $\boldsymbol{X}_{1}, \boldsymbol{X}_{2}, \ldots, \boldsymbol{X}_{\boldsymbol{n}}$ are pairwise independent, then $\operatorname{Var}(X)=\sum_{i} \operatorname{Var}\left(X_{i}\right)$.

## Part II

## Hashing

## Balls and Bins and Load Balancing

Suppose we want to distribute jobs to machines in a simple way to achieve load balancing.

Throwing each new job into a random machine is a simple, distributed, oblivious strategy with many benefits

Balls and bins is simple mathematical model to analyze the core principles

## Balls and Bins $\rightarrow$ Hashing

Hashing:

- Want a "function" $\boldsymbol{h}: \mathcal{U} \rightarrow B$.
- Want $\boldsymbol{h}$ to behave like a "random function". That is for any distinct $x_{1}, x_{2}, \ldots, x_{\boldsymbol{n}} \in \mathcal{U}$ we have $\boldsymbol{h}\left(\boldsymbol{x}_{1}\right), \boldsymbol{h}\left(\boldsymbol{x}_{2}\right), \ldots, \boldsymbol{h}\left(\boldsymbol{x}_{\boldsymbol{n}}\right)$ to be uniformly distributed over $B$ and independent.
- But want $\boldsymbol{h}$ to be efficiently computable and stored in small memory

## Balls and Bins $\rightarrow$ Hashing

Hashing:

- Want a "function" $\boldsymbol{h}: \mathcal{U} \rightarrow B$.
- Want $h$ to behave like a "random function". That is for any distinct $x_{1}, x_{2}, \ldots, x_{\boldsymbol{n}} \in \mathcal{U}$ we have $\boldsymbol{h}\left(\boldsymbol{x}_{1}\right), \boldsymbol{h}\left(x_{2}\right), \ldots, \boldsymbol{h}\left(x_{\boldsymbol{n}}\right)$ to be uniformly distributed over $B$ and independent.
- But want $\boldsymbol{h}$ to be efficiently computable and stored in small memory

Many applications: hash tables as dictionary data structure, cryptography/security, pseudorandomness, . . .

## Dictionary Data Structure

(1) $\mathcal{U}$ : universe of keys: numbers, strings, images, etc.
(2) Data structure to store a subset $S \subseteq \mathcal{U}$
(3) Operations:
(1) Search/look up: given $x \in \mathcal{U}$ is $x \in S$ ?
(2) Insert: given $x \notin S$ add $x$ to $S$.
(3) Delete: given $\boldsymbol{x} \in \boldsymbol{S}$ delete $\boldsymbol{x}$ from $\boldsymbol{S}$
(4) Static structure: $S$ given in advance or changes very infrequently, main operations are lookups.
(5) Dynamic structure: $S$ changes rapidly so inserts and deletes as important as lookups.

## Dictionary Data Structure

- Standard dictionary data structures such binary search trees rely on universe $\mathcal{U}$ being a total order and hence can be compared
- Comparison based data structures take $\Theta(\log n)$ comparisons when storing $\boldsymbol{n}$ items from $\mathcal{U}$ and typically require pointer based data structure
- All objects represented in computers are essentially strings so technically one can use a comparison based data structure always
- Disadvantages of comparison based data structures:
- Comparisons are expensive for many objects
- Dynamic memory allocation and pointers
- Hashing based dictionaries:
- $\boldsymbol{O}(1)$ expected time operations
- Depending on implementation, can avoid pointers

## Hashing and Hash Tables

Hash Table data structure:
(1) A (hash) table/array $\boldsymbol{T}$ of size $\boldsymbol{m}$ (the table size).
(2) A hash function $\boldsymbol{h}: \mathcal{U} \rightarrow\{0, \ldots, \boldsymbol{m}-1\}$.
(3) Item $x \in \mathcal{U}$ hashes to slot $h(x)$ in $T$.

## Hashing and Hash Tables

Hash Table data structure:
(1) A (hash) table/array $\boldsymbol{T}$ of size $\boldsymbol{m}$ (the table size).
(2) A hash function $\boldsymbol{h}: \mathcal{U} \rightarrow\{0, \ldots, \boldsymbol{m}-1\}$.
(3) Item $x \in \mathcal{U}$ hashes to slot $h(x)$ in $T$.

Given $S \subseteq \mathcal{U}$. How do we store $\boldsymbol{S}$ and how do we do lookups?

## Hashing and Hash Tables

Hash Table data structure:
(1) A (hash) table/array $\boldsymbol{T}$ of size $\boldsymbol{m}$ (the table size).
(2) A hash function $\boldsymbol{h}: \mathcal{U} \rightarrow\{0, \ldots, \boldsymbol{m}-1\}$.
(3) Item $x \in \mathcal{U}$ hashes to slot $\boldsymbol{h}(x)$ in $\boldsymbol{T}$.

Given $S \subseteq \mathcal{U}$. How do we store $S$ and how do we do lookups?

## Ideal situation:

(1) Each element $x \in S$ hashes to a distinct slot in $T$. Store $x$ in slot $h(x)$
(2) Lookup: Given $\boldsymbol{y} \in \mathcal{U}$ check if $\boldsymbol{T}[\boldsymbol{h}(\boldsymbol{y})]=\boldsymbol{y}$. $\boldsymbol{O}(1)$ time!

## Hashing and Hash Tables

Hash Table data structure:
(1) A (hash) table/array $\boldsymbol{T}$ of size $\boldsymbol{m}$ (the table size).
(2) A hash function $\boldsymbol{h}: \mathcal{U} \rightarrow\{0, \ldots, \boldsymbol{m}-1\}$.
(3) Item $x \in \mathcal{U}$ hashes to slot $\boldsymbol{h}(x)$ in $\boldsymbol{T}$.

Given $S \subseteq \mathcal{U}$. How do we store $S$ and how do we do lookups?

## Ideal situation:

(1) Each element $x \in S$ hashes to a distinct slot in $T$. Store $x$ in slot $h(x)$
(2) Lookup: Given $\boldsymbol{y} \in \mathcal{U}$ check if $\boldsymbol{T}[\boldsymbol{h}(\boldsymbol{y})]=\boldsymbol{y} . \boldsymbol{O}(1)$ time!

Collisions unavoidable if $|T|<|\mathcal{U}|$. Several techniques to handle them.

## Handling Collisions: Chaining

Collision: $\boldsymbol{h}(x)=\boldsymbol{h}(y)$ for some $x \neq y$.
Chaining/Open hashing to handle collisions:
(1) For each slot $i$ store all items hashed to slot $i$ in a linked list. $T[i]$ points to the linked list
(2) Lookup: to find if $y \in \mathcal{U}$ is in $T$, check the linked list at $T[h(y)]$. Time proportion to size of linked list.

Chain length determines time for operations. Ideally want $O(1)$.

## Hash Functions

Parameters: $N=|\mathcal{U}|$ (very large), $\boldsymbol{m}=|\boldsymbol{T}|, n=|S|$
Goal: $\boldsymbol{O}(1)$-time lookup, insertion, deletion.

## Single hash function

If $\boldsymbol{N} \geq \boldsymbol{m}^{2}$, then for any hash function $\boldsymbol{h}: \mathcal{U} \rightarrow \boldsymbol{T}$ there exists $\boldsymbol{i}<\boldsymbol{m}$ such that at least $\boldsymbol{N} / \boldsymbol{m} \geq \boldsymbol{m}$ elements of $\mathcal{U}$ get hashed to slot $i$.

## Hash Functions

Parameters: $N=|\mathcal{U}|$ (very large), $\boldsymbol{m}=|\boldsymbol{T}|, n=|S|$
Goal: $\boldsymbol{O}(1)$-time lookup, insertion, deletion.

## Single hash function

If $\boldsymbol{N} \geq \boldsymbol{m}^{2}$, then for any hash function $\boldsymbol{h}: \mathcal{U} \rightarrow \boldsymbol{T}$ there exists $\boldsymbol{i}<\boldsymbol{m}$ such that at least $\boldsymbol{N} / \boldsymbol{m} \geq \boldsymbol{m}$ elements of $\mathcal{U}$ get hashed to slot $i$. Any $S$ containing all of these is a very very bad set for $h$ !

## Hash Functions

Parameters: $N=|\mathcal{U}|$ (very large), $\boldsymbol{m}=|\boldsymbol{T}|, n=|S|$
Goal: $\boldsymbol{O}(1)$-time lookup, insertion, deletion.

## Single hash function

If $\boldsymbol{N} \geq \boldsymbol{m}^{2}$, then for any hash function $\boldsymbol{h}: \mathcal{U} \rightarrow \boldsymbol{T}$ there exists $\boldsymbol{i}<\boldsymbol{m}$ such that at least $\boldsymbol{N} / \boldsymbol{m} \geq \boldsymbol{m}$ elements of $\mathcal{U}$ get hashed to slot $i$. Any $S$ containing all of these is a very very bad set for $h$ ! Such a bad set may lead to $\boldsymbol{O}(\boldsymbol{m})$ lookup time!

## Hash Functions

Parameters: $\boldsymbol{N}=|\mathcal{U}|$ (very large), $\boldsymbol{m}=|\boldsymbol{T}|, \boldsymbol{n}=|\boldsymbol{S}|$
Goal: $\boldsymbol{O}(1)$-time lookup, insertion, deletion.

## Single hash function

If $\boldsymbol{N} \geq \boldsymbol{m}^{2}$, then for any hash function $\boldsymbol{h}: \mathcal{U} \rightarrow \boldsymbol{T}$ there exists $\boldsymbol{i}<\boldsymbol{m}$ such that at least $\boldsymbol{N} / \boldsymbol{m} \geq \boldsymbol{m}$ elements of $\mathcal{U}$ get hashed to slot $i$. Any $S$ containing all of these is a very very bad set for $h$ ! Such a bad set may lead to $\boldsymbol{O}(\boldsymbol{m})$ lookup time!

In practice:

- Dictionary applications: choose a simple hash function and hope that worst-case bad sets do not arise
- Crypto applications: create "hard" and "complex" function very carefully which makes finding collisions difficult

## Hashing from a theoretical point of view

- Consider a family $\mathcal{H}$ of hash functions with good properties and choose $\boldsymbol{h}$ randomly from $\mathcal{H}$
- Guarantees: small \# collisions in expectation for any given $S$.
- $\mathcal{H}$ should allow efficient sampling.
- Each $\boldsymbol{h} \in \mathcal{H}$ should be efficient to evaluate and require small memory to store.
In other worse a hash function is a "pseudorandom" function

## Strongly Universal Hashing

Question: What are good properties of $\mathcal{H}$ in distributing data?

## Strongly Universal Hashing

Question: What are good properties of $\mathcal{H}$ in distributing data?
(1) Uniform: Consider any element $x \in \mathcal{U}$. Then if $\boldsymbol{h} \in \mathcal{H}$ is picked randomly then $x$ should go into a random slot in $T$. In other words $\operatorname{Pr}[\boldsymbol{h}(\boldsymbol{x})=\boldsymbol{i}]=1 / \boldsymbol{m}$ for every $0 \leq \boldsymbol{i}<\boldsymbol{m}$.

## Strongly Universal Hashing

Question: What are good properties of $\mathcal{H}$ in distributing data?
(1) Uniform: Consider any element $x \in \mathcal{U}$. Then if $\boldsymbol{h} \in \mathcal{H}$ is picked randomly then $x$ should go into a random slot in $T$. In other words $\operatorname{Pr}[\boldsymbol{h}(\boldsymbol{x})=\boldsymbol{i}]=1 / \boldsymbol{m}$ for every $0 \leq \boldsymbol{i}<\boldsymbol{m}$.
(2) (2)-Strongly Universal: Consider any two distinct elements $\boldsymbol{x}, \boldsymbol{y} \in \mathcal{U}$. Then if $\boldsymbol{h} \in \mathcal{H}$ is picked randomly then $\boldsymbol{h}(\boldsymbol{x})$ and $\boldsymbol{h}(\boldsymbol{y})$ should be independent random variables.

## Strongly Universal Hashing

Question: What are good properties of $\mathcal{H}$ in distributing data?
(1) Uniform: Consider any element $x \in \mathcal{U}$. Then if $\boldsymbol{h} \in \mathcal{H}$ is picked randomly then $x$ should go into a random slot in $T$. In other words $\operatorname{Pr}[\boldsymbol{h}(\boldsymbol{x})=\boldsymbol{i}]=1 / \boldsymbol{m}$ for every $0 \leq \boldsymbol{i}<\boldsymbol{m}$.
(2) (2)-Strongly Universal: Consider any two distinct elements $\boldsymbol{x}, \boldsymbol{y} \in \mathcal{U}$. Then if $\boldsymbol{h} \in \mathcal{H}$ is picked randomly then $\boldsymbol{h}(\boldsymbol{x})$ and $\boldsymbol{h}(\boldsymbol{y})$ should be independent random variables.
Note: Fix $x \in \mathcal{U} . \boldsymbol{h}(\boldsymbol{x})$ is a random variable with range $\{0,1,2, \ldots, m-1\}$. Strong universal hash family implies that the variables $h(x), x \in S$ are uniform and pairwise independent random variables.

## Universal Hashing

Question: What are good properties of $\mathcal{H}$ in distributing data?

- (2)-Universal: Consider any two distinct elements $x, y \in \mathcal{U}$. Then if $\boldsymbol{h} \in \mathcal{H}$ is picked randomly then the probability of a collision between $x$ and $y$ should be at most $1 / \boldsymbol{m}$. In other words $\operatorname{Pr}[\boldsymbol{h}(\boldsymbol{x})=\boldsymbol{h}(\boldsymbol{y})] \leq 1 / \boldsymbol{m}$.
Note: we do not insist on uniformity.

## (Strongly) Universal Hashing

## Definition

A family of hash functions $\mathcal{H}$ is (2-)strongly universal if for all distinct $\boldsymbol{x}, \boldsymbol{y} \in \mathcal{U}, \boldsymbol{h}(\boldsymbol{x})$ and $\boldsymbol{h}(\boldsymbol{y})$ are independent for $\boldsymbol{h}$ chosen uniformly at random from $\mathcal{H}$, and for all $\boldsymbol{x}, \boldsymbol{h}(\boldsymbol{x})$ is uniformly distributed.

## Definition

A family of hash functions $\mathcal{H}$ is (2-)universal if for all distinct $\boldsymbol{x}, \boldsymbol{y} \in \mathcal{U}, \operatorname{Pr}_{\boldsymbol{h} \sim \mathcal{H}}[\boldsymbol{h}(\boldsymbol{x})=\boldsymbol{h}(\boldsymbol{y})] \leq 1 / \boldsymbol{m}$ where $\boldsymbol{m}$ is the table size.

## (Strongly) Universal Hashing

## Definition

A family of hash functions $\mathcal{H}$ is (2-)strongly universal if for all distinct $\boldsymbol{x}, \boldsymbol{y} \in \mathcal{U}, \boldsymbol{h}(\boldsymbol{x})$ and $\boldsymbol{h}(\boldsymbol{y})$ are independent for $\boldsymbol{h}$ chosen uniformly at random from $\mathcal{H}$, and for all $\boldsymbol{x}, \boldsymbol{h}(\boldsymbol{x})$ is uniformly distributed.

## Definition

A family of hash functions $\mathcal{H}$ is (2-)universal if for all distinct $\boldsymbol{x}, \boldsymbol{y} \in \mathcal{U}, \operatorname{Pr}_{\boldsymbol{h} \sim \mathcal{H}}[\boldsymbol{h}(\boldsymbol{x})=\boldsymbol{h}(\boldsymbol{y})] \leq 1 / \boldsymbol{m}$ where $\boldsymbol{m}$ is the table size.

Generalizes to $t$-strongly universal and $t$-universal families. Need property for any tuple of $t$ items.

## Analyzing Universal Hashing

Question: Fixing set $S$, what is the expected time to look up $x \in S$ when $\boldsymbol{h}$ is picked uniformly at random from $\mathcal{H}$ ?
(1) $\ell(x)$ : the size of the list at $T[\boldsymbol{h}(x)]$. We want $\mathrm{E}[\ell(x)]$
(2) For $y \in S$ let $D_{y}=1$ if $\boldsymbol{h}(y)=\boldsymbol{h}(x)$, else 0 . $\ell(x)=\sum_{y \in S} D_{y}$

## Analyzing Universal Hashing

Question: Fixing set $S$, what is the expected time to look up $x \in S$ when $\boldsymbol{h}$ is picked uniformly at random from $\mathcal{H}$ ?
(1) $\ell(x)$ : the size of the list at $T[\boldsymbol{h}(x)]$. We want $\mathrm{E}[\ell(x)]$
(2) For $y \in S$ let $D_{y}=1$ if $\boldsymbol{h}(y)=\boldsymbol{h}(x)$, else 0 . $\ell(x)=\sum_{y \in S} D_{y}$

$$
\begin{aligned}
\mathrm{E}[\ell(x)] & =\sum_{y \in S} \mathrm{E}\left[D_{y}\right]=\sum_{y \in S} \operatorname{Pr}[\boldsymbol{h}(x)=\boldsymbol{h}(y)] \\
& \leq 1+\sum_{y \in S, y \neq x} \frac{1}{m} \quad(\mathcal{H} \text { is a universal hash family }) \\
& \leq 1+(|S|-1) / m \leq 2 \quad \text { if }|S| \leq m
\end{aligned}
$$

## Analyzing Universal Hashing

Question: What is the expected time to look up $x$ in $T$ using $h$ assuming chaining used to resolve collisions?

Answer: $O(n / m)$.

## Analyzing Universal Hashing

Question: What is the expected time to look up $x$ in $T$ using $h$ assuming chaining used to resolve collisions?

Answer: $O(n / m)$.
Comments:
(1) $O(1)$ expected time also holds for insertion.
(2) Analysis assumes static set $S$ but holds as long as $S$ is a set formed with at most $O(\boldsymbol{m})$ insertions and deletions.
(3) Worst-case: look up time can be large! How large? In principle $\Omega(\boldsymbol{n})$ time but if $\mathcal{H}$ has good properties then $O(\sqrt{\boldsymbol{n}})$ or $O(\log n / \log \log n)$ with high probability.

## Universal Hash Family

Universal: $\mathcal{H}$ such that $\operatorname{Pr}[\boldsymbol{h}(\boldsymbol{x})=\boldsymbol{h}(\boldsymbol{y})]=1 / \boldsymbol{m}$.

## All functions

$\mathcal{H}$ : Set of all possible functions $\boldsymbol{h}: \mathcal{U} \rightarrow\{0, \ldots, \boldsymbol{m}-1\}$.

- Universal.

## Universal Hash Family

Universal: $\mathcal{H}$ such that $\operatorname{Pr}[\boldsymbol{h}(\boldsymbol{x})=\boldsymbol{h}(\boldsymbol{y})]=1 / \boldsymbol{m}$.

## All functions

$\mathcal{H}$ : Set of all possible functions $\boldsymbol{h}: \mathcal{U} \rightarrow\{0, \ldots, \boldsymbol{m}-1\}$.

- Universal.
- $|\mathcal{H}|=\boldsymbol{m}^{|\mathcal{U}|}$
- representing $\boldsymbol{h}$ requires $|\mathcal{U}| \log \boldsymbol{m}$ - Not $\boldsymbol{O}(1)$ !

## Universal Hash Family

Universal: $\mathcal{H}$ such that $\operatorname{Pr}[\boldsymbol{h}(\boldsymbol{x})=\boldsymbol{h}(\boldsymbol{y})]=1 / \boldsymbol{m}$.

## All functions

$\mathcal{H}$ : Set of all possible functions $\boldsymbol{h}: \mathcal{U} \rightarrow\{0, \ldots, \boldsymbol{m}-1\}$.

- Universal.
- $|\mathcal{H}|=\boldsymbol{m}^{|\mathcal{U}|}$
- representing $\boldsymbol{h}$ requires $|\mathcal{U}| \log \boldsymbol{m}$ - Not $\boldsymbol{O}(1)$ !

We need compactly representable universal family.

## Compact Stongly Universal Hash Family

Similar to construction of $N$ pairwise independent random variables with range $[m]$.

The function is given by the algorithm to construct $\boldsymbol{X}_{\boldsymbol{i}}$ given $\boldsymbol{i}$.
Can do with $O(\log N)$ bits of storage since $N \geq m$ in hashing application.

## A Compact Universal Hash Family

Parameters: $\boldsymbol{N}=|\mathcal{U}|, \boldsymbol{m}=|\boldsymbol{T}|, \boldsymbol{n}=|\boldsymbol{S}|$. Assumption $\boldsymbol{m} \leq N$.
(1) Choose a prime number $\boldsymbol{p} \geq \boldsymbol{N} . \mathbb{Z}_{\boldsymbol{p}}=\{0,1, \ldots, \boldsymbol{p}-1\}$ is a field.
(2) For $\boldsymbol{a}, \boldsymbol{b} \in \mathbb{Z}_{\boldsymbol{p}}, \boldsymbol{a} \neq 0$, define the hash function $\boldsymbol{h}_{\boldsymbol{a}, \boldsymbol{b}}$ as $\boldsymbol{h}_{\boldsymbol{a}, \boldsymbol{b}}(\boldsymbol{x})=((\boldsymbol{a x}+\boldsymbol{b}) \bmod \boldsymbol{p}) \bmod \boldsymbol{m}$.
(3) Let $\mathcal{H}=\left\{h_{a, b} \mid a, b \in \mathbb{Z}_{\boldsymbol{p}}, a \neq 0\right\}$. Note that $|\mathcal{H}|=p(p-1)$.

## A Compact Universal Hash Family

Parameters: $\boldsymbol{N}=|\mathcal{U}|, \boldsymbol{m}=|\boldsymbol{T}|, \boldsymbol{n}=|S|$. Assumption $\boldsymbol{m} \leq \boldsymbol{N}$.
(1) Choose a prime number $p \geq N . \mathbb{Z}_{\boldsymbol{p}}=\{0,1, \ldots, p-1\}$ is a field.
(2) For $\boldsymbol{a}, \boldsymbol{b} \in \mathbb{Z}_{\boldsymbol{p}}, \boldsymbol{a} \neq 0$, define the hash function $\boldsymbol{h}_{\boldsymbol{a}, \boldsymbol{b}}$ as $\boldsymbol{h}_{\boldsymbol{a}, \boldsymbol{b}}(\boldsymbol{x})=((\boldsymbol{a x}+\boldsymbol{b}) \bmod \boldsymbol{p}) \bmod \boldsymbol{m}$.
(3) Let $\mathcal{H}=\left\{h_{a, b} \mid a, b \in \mathbb{Z}_{\boldsymbol{p}}, a \neq 0\right\}$. Note that $|\mathcal{H}|=p(p-1)$.

## Theorem

$\mathcal{H}$ is a universal hash family.

## A Compact Universal Hash Family

Parameters: $\boldsymbol{N}=|\mathcal{U}|, \boldsymbol{m}=|\boldsymbol{T}|, \boldsymbol{n}=|\boldsymbol{S}|$. Assumption $\boldsymbol{m} \leq \boldsymbol{N}$.
(1) Choose a prime number $p \geq N . \mathbb{Z}_{\boldsymbol{p}}=\{0,1, \ldots, p-1\}$ is a field.
(2) For $\boldsymbol{a}, \boldsymbol{b} \in \mathbb{Z}_{\boldsymbol{p}}, \boldsymbol{a} \neq 0$, define the hash function $\boldsymbol{h}_{\boldsymbol{a}, \boldsymbol{b}}$ as $\boldsymbol{h}_{\boldsymbol{a}, \boldsymbol{b}}(\boldsymbol{x})=((\boldsymbol{a x}+\boldsymbol{b}) \bmod \boldsymbol{p}) \bmod \boldsymbol{m}$.
(3) Let $\mathcal{H}=\left\{h_{a, b} \mid a, b \in \mathbb{Z}_{\boldsymbol{p}}, a \neq 0\right\}$. Note that $|\mathcal{H}|=p(p-1)$.

## Theorem

$\mathcal{H}$ is a universal hash family.
Comments:
(1) Hash family is of small size, easy to sample from.
(2) Easy to store a hash function ( $\boldsymbol{a}, \boldsymbol{b}$ have to be stored) and evaluate it.

## A Compact Universal Hash Family

- $g(x)=\boldsymbol{a x}+\boldsymbol{b}$ is uniformly distributed in $\{0,1, \ldots, \boldsymbol{p}-1\}$ but $h(x)$ is not uniformly distributed unless $m=p$.
- $\operatorname{Pr}[\boldsymbol{h}(\boldsymbol{x})=\boldsymbol{i}] \leq 2 / \boldsymbol{m}$ for any $\boldsymbol{i}$.

## Bloom Filters

## Hashing:

(1) To insert $x$ in dictionary store $x$ in table in location $h(x)$
(2) To lookup $y$ in dictionary check contents of location $\boldsymbol{h}(\boldsymbol{y})$

## Bloom Filters

## Hashing:

(1) To insert $x$ in dictionary store $x$ in table in location $h(x)$
(2) To lookup $\boldsymbol{y}$ in dictionary check contents of location $\boldsymbol{h}(\boldsymbol{y})$

Bloom Filter: tradeoff space for false positives
(1) Storing items in dictionary expensive in terms of memory, especially if items are unwieldy objects such a long strings, images, etc with non-uniform sizes.
(2) To insert $x$ in dictionary set bit to 1 in location $\boldsymbol{h}(x)$ (initially all bits are set to 0 )
(3) To lookup $\boldsymbol{y}$ if bit in location $\boldsymbol{h}(\boldsymbol{y})$ is 1 say yes, else no.

## Bloom Filters

## Bloom Filters

Bloom Filter: tradeoff space for false positives
(1) To insert $\boldsymbol{x}$ in dictionary set bit to 1 in location $\boldsymbol{h}(\boldsymbol{x})$ (initially all bits are set to 0 )
(2) To lookup $\boldsymbol{y}$ if bit in location $\boldsymbol{h}(\boldsymbol{y})$ is 1 say yes, else no
(3) No false negatives but false positives possible due to collisions

Reducing false positives:
(1) Pick $\boldsymbol{k}$ hash functions $\boldsymbol{h}_{1}, \boldsymbol{h}_{2}, \ldots, \boldsymbol{h}_{\boldsymbol{k}}$ independently
(2) To insert $\boldsymbol{x}$, for each $\boldsymbol{i}$, set bit in location $\boldsymbol{h}_{\boldsymbol{i}}(\boldsymbol{x})$ in table $\boldsymbol{i}$ to 1
(3) To lookup $\boldsymbol{y}$ compute $\boldsymbol{h}_{\boldsymbol{i}}(\boldsymbol{y})$ for $1 \leq \boldsymbol{i} \leq \boldsymbol{k}$ and say yes only if each bit in the corresponding location is 1 , otherwise say no. If probability of false positive for one hash function is $\boldsymbol{\alpha}<1$ then with $\boldsymbol{k}$ independent hash function it is $\boldsymbol{\alpha}^{\boldsymbol{k}}$.

## Take away points

(1) Hashing is a powerful and important technique for dictionaries. Many practical applications.
(2) Randomization fundamental to understanding hashing.
(3) Good and efficient hashing possible in theory and practice with proper definitions (universal, perfect, etc).
(4) Related ideas of creating a compact fingerprint/sketch for objects is very powerful in theory and practice.

## Practical Issues

Hashing used typically for integers, vectors, strings etc.

- Universal hashing is defined for integers. To implement for other objects need to map objects in some fashion to integers (via representation)
- Practical methods for various important cases such as vectors, strings are studied extensively. See http://en.wikipedia.org/wiki/Universal_hashing for some pointers.
- Details on Cuckoo hashing and its advantage over chaining http://en.wikipedia.org/wiki/Cuckoo_hashing.
- Recent important paper bridging theory and practice of hashing. "The power of simple tabulation hashing" by Mikkel Thorup and Mihai Patrascu, 2011. See http://en.wikipedia.org/wiki/Tabulation_hashing
