Temporal Classification Example: Speech

Temporal classification maps from a sequence of speech frames (top) to a sequence of phoneme or character labels (bottom).

Graves et al., 2006, Figure 1. (c) ICML

Variables in CTC

- $\mathbf{x} = [x_1, \dots, x_T]$ is the input. It is a sequence of vectors, $x_t = [x_1^t, \dots, x_m^t]$.
- y = [y₁,..., y_T] is the network output. It is a sequence of probability vectors, y_u = [y₁^u,..., y_{|L|+1}].

• $\pi = [\pi_1, \dots, \pi_T]$ is the path. It is a sequence of characters,

$$y_k^t = p(\pi_t = k | \mathbf{x})$$

I = [I₁,..., I_U] = B(π) is the label sequence, U ≤ T, which should be compared to the correct label sequence, z.

CTC Forward Algorithm: The Modified Label Sequence

In order to express the CTC forward algorithm, we need to define a modified label sequence, \mathbf{I}' . \mathbf{I}' is equal to \mathbf{I} with blanks inserted between every pair of letters. Thus if

$$\boldsymbol{I}=[\boldsymbol{f},\boldsymbol{e},\boldsymbol{d}],$$

then

$$\boldsymbol{\mathsf{I}}'=[-,\mathsf{f},-,\mathsf{e},-,\mathsf{d},-].$$

If the length of \mathbf{I} is $|\mathbf{I}|$, then the length of \mathbf{I}' is $2|\mathbf{I}| + 1$.

CTC Forward Algorithm: Partial Sequences

We also need to define the following partial sequences:

$$\begin{aligned} \mathbf{x}_{1:t} &= [x_1, \dots, x_t] \\ \pi_{1:t} &= [\pi_1, \dots, \pi_t] \\ \mathbf{l'}_{1:s} &= [l'_1, \dots, l'_s] \\ &= \begin{cases} \begin{bmatrix} -, l_1, -, l_2, \dots, l_{s/2} \end{bmatrix} & s \text{ even} \\ \begin{bmatrix} -, l_1, -, l_2, \dots, l_{(s-1)/2}, - \end{bmatrix} & s \text{ odd} \end{cases} \end{aligned}$$

Maximum Likelihood Training of a CTC Network

Summary 00

The CTC Forward Algorithm

Definition:

$$\alpha_t(\mathbf{I}'_{1:s}) \equiv p(\mathbf{I}'_{1:s}|\mathbf{x}_{1:t})$$

Maximum Likelihood Training of a CTC Network

Summary 00

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

The CTC Forward Algorithm

Initialize:

$$\alpha_t([-]) = y_-^1$$

$$\alpha_t([-, l_1]) = y_{l_1}^1$$

Iterate:

$$\alpha_{t}(\mathbf{I}'_{1:s}) = \begin{cases} (\alpha_{t-1}(\mathbf{I}'_{1:s}) + \alpha_{t-1}(\mathbf{I}'_{1:s-1})) \times y_{l'_{s}}^{t} \\ \dots \dots \dots & \text{if } l'_{s} = -\text{ or } l'_{s} = l'_{s-2} \\ (\alpha_{t-1}(\mathbf{I}'_{1:s}) + \alpha_{t-1}(\mathbf{I}'_{1:s-1}) + \alpha_{t-1}(\mathbf{I}'_{1:s-2})) \times y_{l'_{s}}^{t} \\ \dots \dots \dots & \text{otherwise} \end{cases}$$

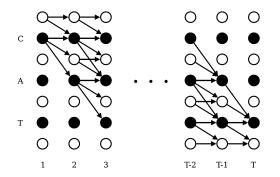

O Terminate:

$$p(\mathbf{I}_{1:U}|\mathbf{x}) = \alpha_{\mathcal{T}}(\mathbf{I}'_{1:2U}) + \alpha_{\mathcal{T}}(\mathbf{I}'_{1:2U+1})$$

2 Maximum Likelihood Training of a CTC Network

The CTC Loss

The CTC loss function is the negative log probability of the correct label sequence given the waveform:

$$\mathcal{L}_{\mathsf{CTC}} = -\ln p(\mathbf{z}|\mathbf{x})$$

This is similar to cross entropy, but differentiating it is more complicated, since the correct label sequence is $\mathbf{z} = [z_1, \dots, z_U]$, while the speech sequence is $\mathbf{x} = [x_1, \dots, x_T]$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Probability of Labels Given Speech

- We want to train the network to maximize the probability of the correct labeling, p(z|x).
- The most computationally efficient way to calculate $p(\mathbf{z}|\mathbf{x})$ is the forward algorithm:

$$p(\mathbf{z}|\mathbf{x}) = \alpha_T(\mathbf{z}'_{1:2U}) + \alpha_T(\mathbf{z}'_{1:2U+1}),$$

... but that form is not easy to differentiate.

• The expansion over all possible paths is not a computationally efficient way to calculate $p(\mathbf{z}|\mathbf{x})$, but it's easier to differentiate:

$$p(\mathbf{z}|\mathbf{x}) = \sum_{\pi \in \mathcal{B}^{-1}(\mathbf{z})} p(\pi|\mathbf{x}) = \sum_{\pi \in \mathcal{B}^{-1}(\mathbf{z})} \prod_{t=1}^{T} y_{\pi_t}^t$$

Differentiating the CTC Loss

Remember that the basic principle of back-propagation is the chain rule. If we want $\frac{d\mathcal{L}}{dw}$, we can find it as

$$\frac{d\mathcal{L}}{dw} = \sum_{\tau=1}^{T} \sum_{k=1}^{|\mathcal{L}|+1} \left(\frac{d\mathcal{L}}{dy_{k}^{\tau}}\right) \left(\frac{\partial y_{k}^{\tau}}{\partial w}\right),$$

 ^{∂y^τ_k}/_{∂w} is the same as for any other RNN, so it's uninteresting.

 ^{dL}/_{dy^τ_k} is unique to CTC. Let's derive it.

Maximum Likelihood Training of a CTC Network

Summary 00

Differentiating the CTC Loss

$$\mathcal{L}_{\mathsf{CTC}} = -\ln p(\mathbf{z}|\mathbf{x}) = -\ln \left(\sum_{\pi \in \mathcal{B}^{-1}(\mathbf{z})} \prod_{t=1}^{T} y_{\pi_t}^t\right)$$

Therefore

$$\frac{d\mathcal{L}}{dy_k^{\tau}} = \left(\frac{-1}{p(\mathbf{z}|\mathbf{x})}\right) \left(\frac{dp(\mathbf{z}|\mathbf{x})}{dy_k^{\tau}}\right) = \left(\frac{-1}{p(\mathbf{z}|\mathbf{x})}\right) \left(\frac{1}{y_k^{\tau}} \sum_{\pi \in \mathcal{B}^{-1}(\mathbf{z}), \pi_{\tau} = k} \prod_{t=1}^{T} y_{\pi_t}^t\right)$$

- The sum in the last line is over all paths that are valid expansions of the correct transcription, and for which π_τ = k.
- The $\frac{1}{y_k^{\tau}}$ comes from the derivative of the product:

$$\frac{d}{dy}xyz = xz = \frac{1}{y}xyz$$

Maximum Likelihood Training of a CTC Network

Summary 00

Differentiating the CTC Loss

$$\frac{d\mathcal{L}}{dy_k^{\tau}} = \left(\frac{-1}{p(\mathbf{z}|\mathbf{x})}\right) \left(\frac{1}{y_k^{\tau}} \sum_{\pi \in \mathcal{B}^{-1}(\mathbf{z}), \pi_{\tau} = k} \prod_{t=1}^{T} y_{\pi_t}^t\right)$$

The sum in the last line is over all paths that are valid expansions of the correct transcription, and for which $\pi_{\tau} = k$. This has a nice Bayesian interpretation:

$$\begin{aligned} \frac{d\mathcal{L}}{dy_k^{\tau}} &= \left(\frac{-1}{p(\mathbf{z}|\mathbf{x})}\right) \left(\frac{1}{y_k^{\tau}} p(\mathbf{z}, \pi_{\tau} = k | \mathbf{x})\right) \\ &= \frac{-1}{y_k^{\tau}} p(\pi_{\tau} = k | \mathbf{z}, \mathbf{x}) \end{aligned}$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

The CTC Gamma Probability

Just as for any other HMM, let's define a gamma probability, $\gamma_{\tau}(k) = p(\pi_{\tau} = k, \mathbf{z} | \mathbf{x})$. Then

$$\frac{d\mathcal{L}}{dy_k^{\tau}} = -\frac{\gamma_{\tau}(k)}{y_k^{\tau}},$$

where

$$\gamma_{\tau}(k) = p(\pi_{\tau} = k, \mathbf{z} | \mathbf{x}) = \frac{1}{y_{k}^{\tau}} \sum_{s: \mathbf{z}_{s}' = k} \alpha_{\tau}(\mathbf{z}'_{1:s}) \beta_{\tau}(\mathbf{z}'_{s:(2U+1)}) \quad (1)$$

•
$$\beta_t(\mathbf{z}'_{s:2U+1}) = p(\mathbf{z}'_{s:(2U+1)}|\mathbf{x}_{t:T})$$

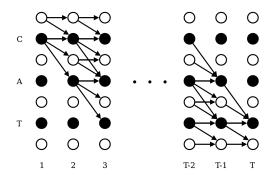

Notice that α_τ(z'_{1:s}) and β_τ(z'_{s:(2U+1)} both include the fact that the network is producing z'_s = k at time τ. To compensate for that duplication, Eq. (1) has a ¹/_{Y^T} factor.

・ロト・西ト・田・・田・ ひゃぐ

Maximum Likelihood Training of a CTC Network

Summary 00

The CTC Forward-Backward Algorithm

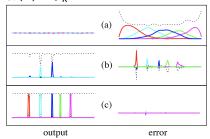

Graves et al., 2006, Fig. 3. (c) ICML

 $\alpha_t(\mathbf{z}'_{1:s})$ is the probability of the best path up to (and including) state z'_s at time t. $\beta_t(\mathbf{z}'_{s:(2U+1)})$ is the probability of the best path starting from state z'_s at time t.

- At the start of training (a), y_k^t = 0 for all k except the blank symbol. γ_t(k), is determined mostly by the known sequence of the correct labels, z.
- After some training (b), y^t_k has started to converge. Its convergence guides the forward-backward algorithm, so γ_t(k) is also much more localized.
- When fully converged, y^t_k ≈ γ_t(k), so the error is nearly zero.

Left column: network outputs y_k^t . Right column: error signal $\gamma_t(k) - y_k^t$.

Conclusions

• A CTC network is trained to minimize

$$\mathcal{L}_{CTC} = -\ln \mathit{p}(\mathbf{z}|\mathbf{x})$$

• Differentiating, we discover that

$$rac{d\mathcal{L}}{dy_k^ au} = rac{1}{y_k^ au} p(\pi_ au = k | \mathbf{z}, \mathbf{x})$$

- $p(\pi_{\tau} = k | \mathbf{z}, \mathbf{x})$ can be computed using the forward-backward algorithm.
- Even in the very first epoch of training, the known sequence z distributes error uniformly across the waveform. For this reason, CTC training converges smoothly and quickly (compared, e.g., to Transformer loss).
