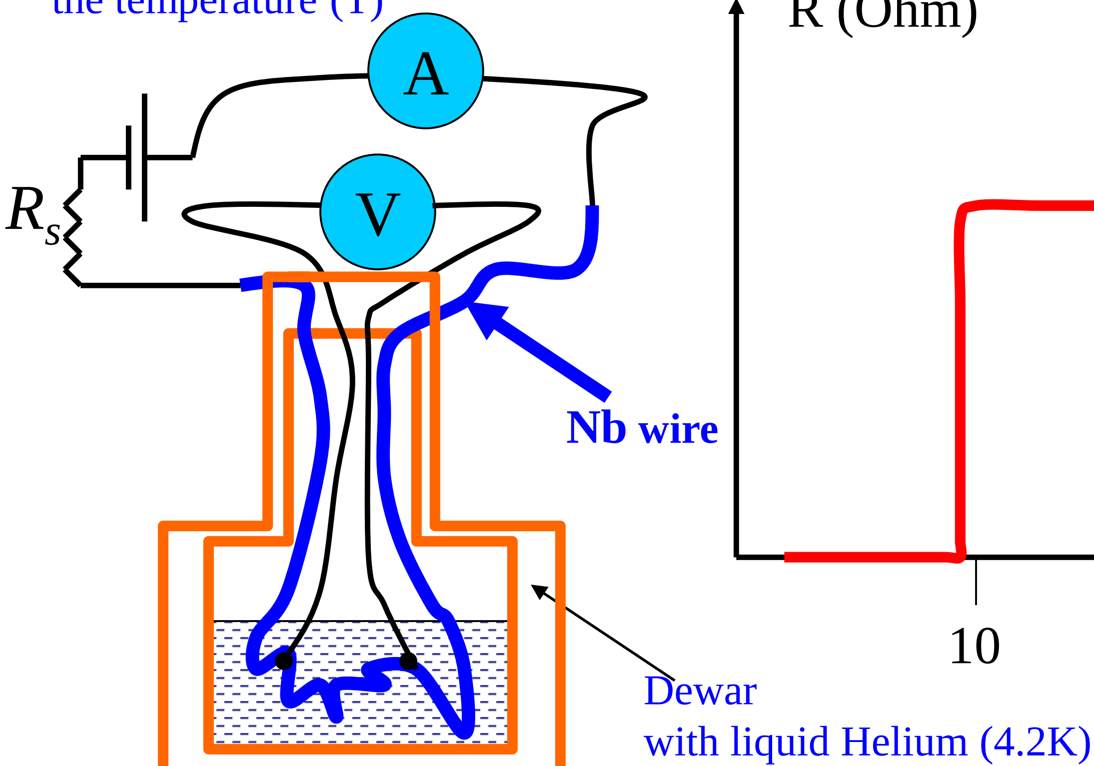
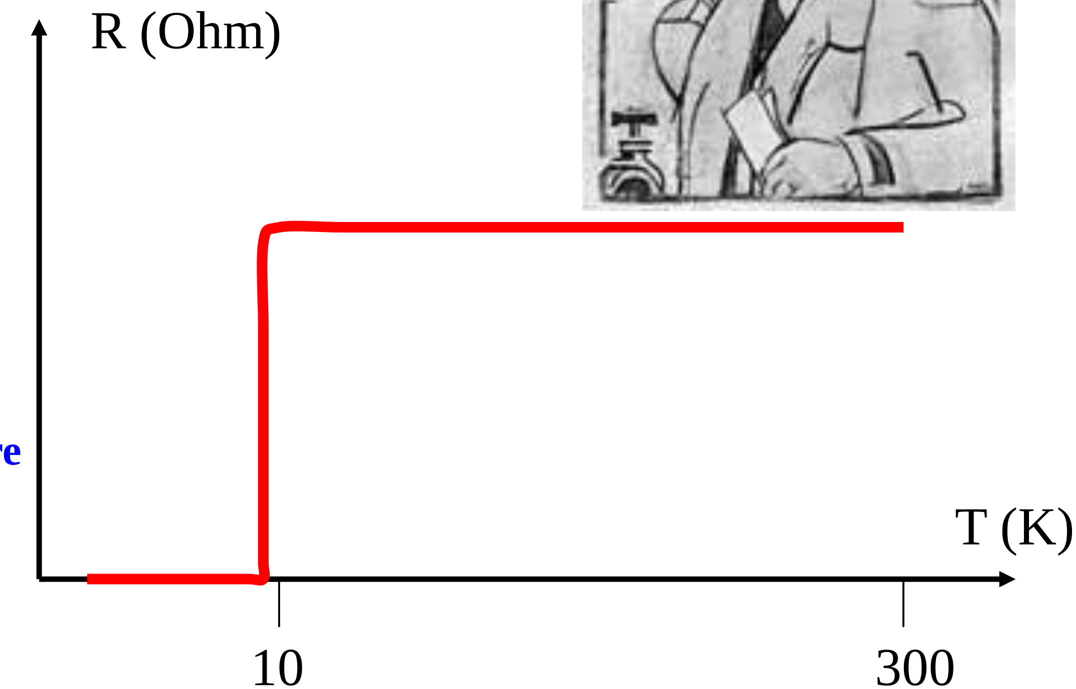
How to measure superconductivity

Electrical resistance of some metals drops to zero below a certain temperature which is called "critical temperature“ (H. K. O. 1911)

How to observe superconductivity

1. Take Nb (niobium) wire
2. Connect to a voltmeter and a current source
3. Immerse into helium Dewar (T=4.2 K boiling point)
4. Measure electrical resistance (R) versus the temperature (T)





Heike Kamerling Onnes

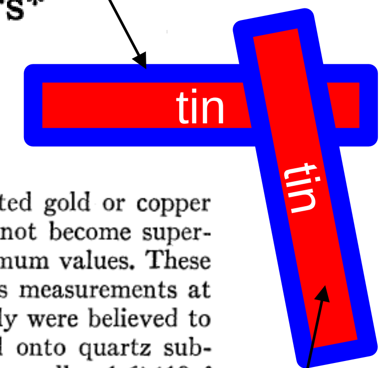
Discovery of the supercurrent, known now as proximity effect, in SNS junctions

PHYSICAL REVIEW VOLUME 117, NUMBER 3 FEBRUARY 1, 1960



Superconductivity of Contacts with Interposed Barriers*

HANS MEISSNER†
Department of Physics, The Johns Hopkins University, Baltimore, Maryland

(Received August 25, 1959)

Resistance *vs* current diagrams and "Diagrams of State" have been obtained for 63 contacts between crossed wires of tin. The wires were plated with various thicknesses of the following metals: copper, silver, gold, chromium, iron, cobalt, nickel, and platinum. The contacts became superconducting, or showed a noticeable decrease of their resistance at lower temperatures if the plated films were not too thick. The limiting thicknesses were about 35×10^{-6} cm for Cu, Ag, and Au; 7.5×10^{-6} cm for Pt, 4×10^{-6} cm for Cr, and less than 2×10^{-6} cm for the ferromagnetic metals Fe, Co, and Ni. The investigation was extended to measurements of the resistance of contacts between crossed wires of copper or gold plated with various thicknesses of tin. Simultaneous measurements of the (longitudinal) resistance of the tin-plated gold or copper wires showed that these thin films of tin do not become superconducting for thicknesses below certain minimum values. These latter findings are in agreement with previous measurements at Toronto. The measurements at Toronto usually were believed to be unreliable because films of tin evaporated onto quartz substrates can be superconducting at thicknesses as small as 1.6×10^{-6} cm. It is now believed that just as superconducting electrons can drift into an adjoining normal conducting layer and make it superconducting, normal electrons can drift into an adjoining superconducting layer and prevent superconductivity.

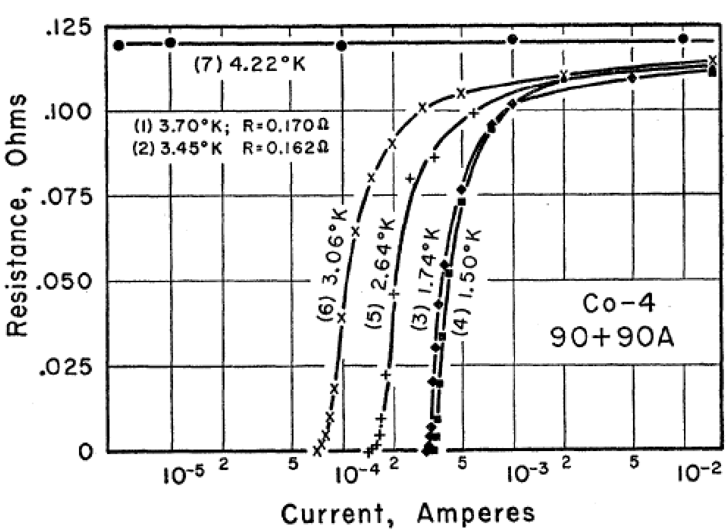


FIG. 1. Resistance *vs* current diagram of cobalt-plated contact Co 4, representative of diagrams type A.

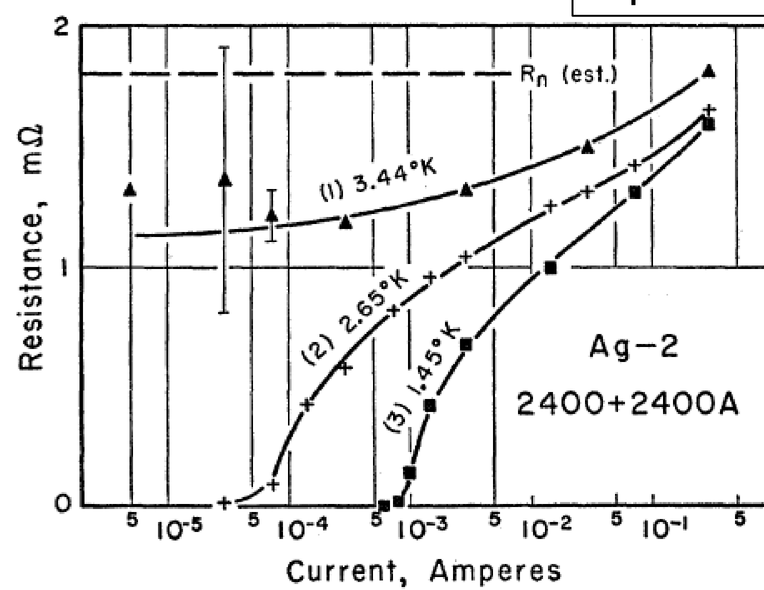

FIG. 2. Resistance *vs* current diagram of silver-plated contact Ag 2, representative of diagrams type B.

Non-Abelian Majorana Modes in Vortices

VOLUME 86, NUMBER 2 PHYSICAL REVIEW LETTERS 8 JANUARY 2001

Non-Abelian Statistics of Half-Quantum Vortices in *p*-Wave Superconductors

D. A. Ivanov
Institut für Theoretische Physik, ETH-Hönggerberg, CH-8093 Zürich, Switzerland
(Received 17 May 2000)

Excitation spectrum of a half-quantum vortex in a *p*-wave superconductor contains a zero-energy Majorana fermion. This results in a degeneracy of the ground state of the system of several vortices. From the properties of the solutions to Bogoliubov–de Gennes equations in the vortex core we derive the non-Abelian statistics of vortices identical to that for the Moore-Read (Pfaffian) quantum Hall state.

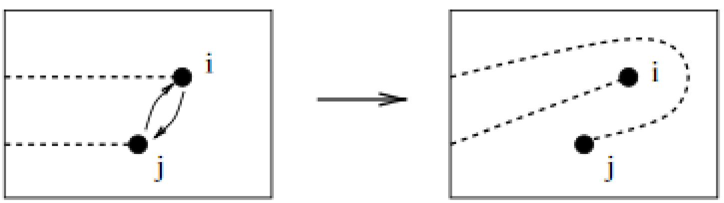

FIG. 3. Elementary braid interchange of two vortices.

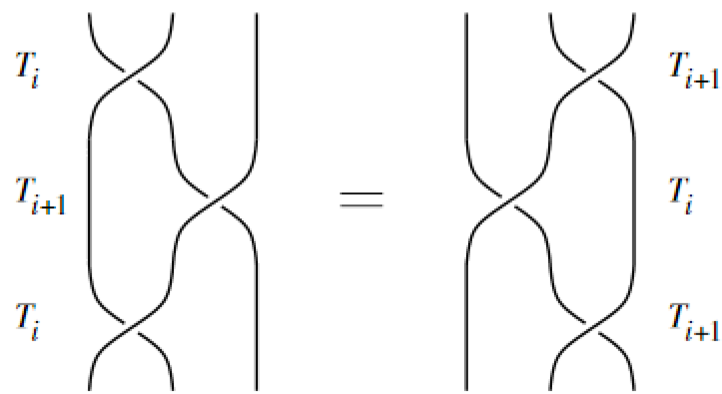

FIG. 2. Defining relation for the braid group: $T_i T_{i+1} T_i = T_{i+1} T_i T_{i+1}$.

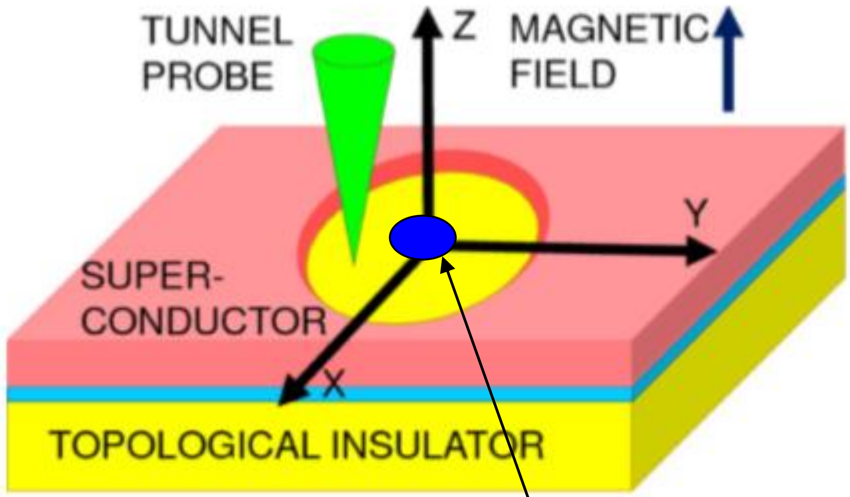
Total number of quantum states
for N pairs of such Majorana vortices is:
2^N
Example N=100
$2^{100}=10^{30}$

Majorana modes in a vortex



Theory: Vortex in the nano-hole contains Majorana states (gap is about Tc)

SQUID – superconducting quantum interference device

SQUID helmet project at Los Alamos

Magnetic field scales:

Earth field: ~1G

Fields inside animals: ~0.01G-0.00001G

Fields on the **human brain**: ~0.3nG
This is less than a hundred-millionth of the Earth's magnetic field.

SQUIDs, or Superconducting Quantum Interference Devices, invented in 1964 by Robert Jaklevic, John Lambe, Arnold Silver, and James Mercereau of Ford Scientific Laboratories, are used to measure extremely small magnetic fields. They are currently the most sensitive magnetometers known, with the noise level as low as 3 fT•Hz−½. While, for example, the Earth magnet field is only about 0.0001 Tesla, some electrical processes in animals produce very small magnetic fields, typically between 0.000001 Tesla and 0.000000001 Tesla. SQUIDs are especially well suited for studying magnetic fields this small.
Measuring the brain's magnetic fields is even much more difficult because just above the skull the strength of the magnetic field is only about 0.3 picoTesla (0.0000000000003 Tesla). This is less than a hundred-millionth of Earth's magnetic field. In fact, brain fields can be measured only with the most sensitive magnetic-field sensor, i.e. with the superconducting quantum interference device, or SQUID.

Vortices introduce electrical resistence to otherwise superconducting materials

Magnetic field creates vortices--

Vortices cause dissipation (i.e. a non-zero electrical resistance)!

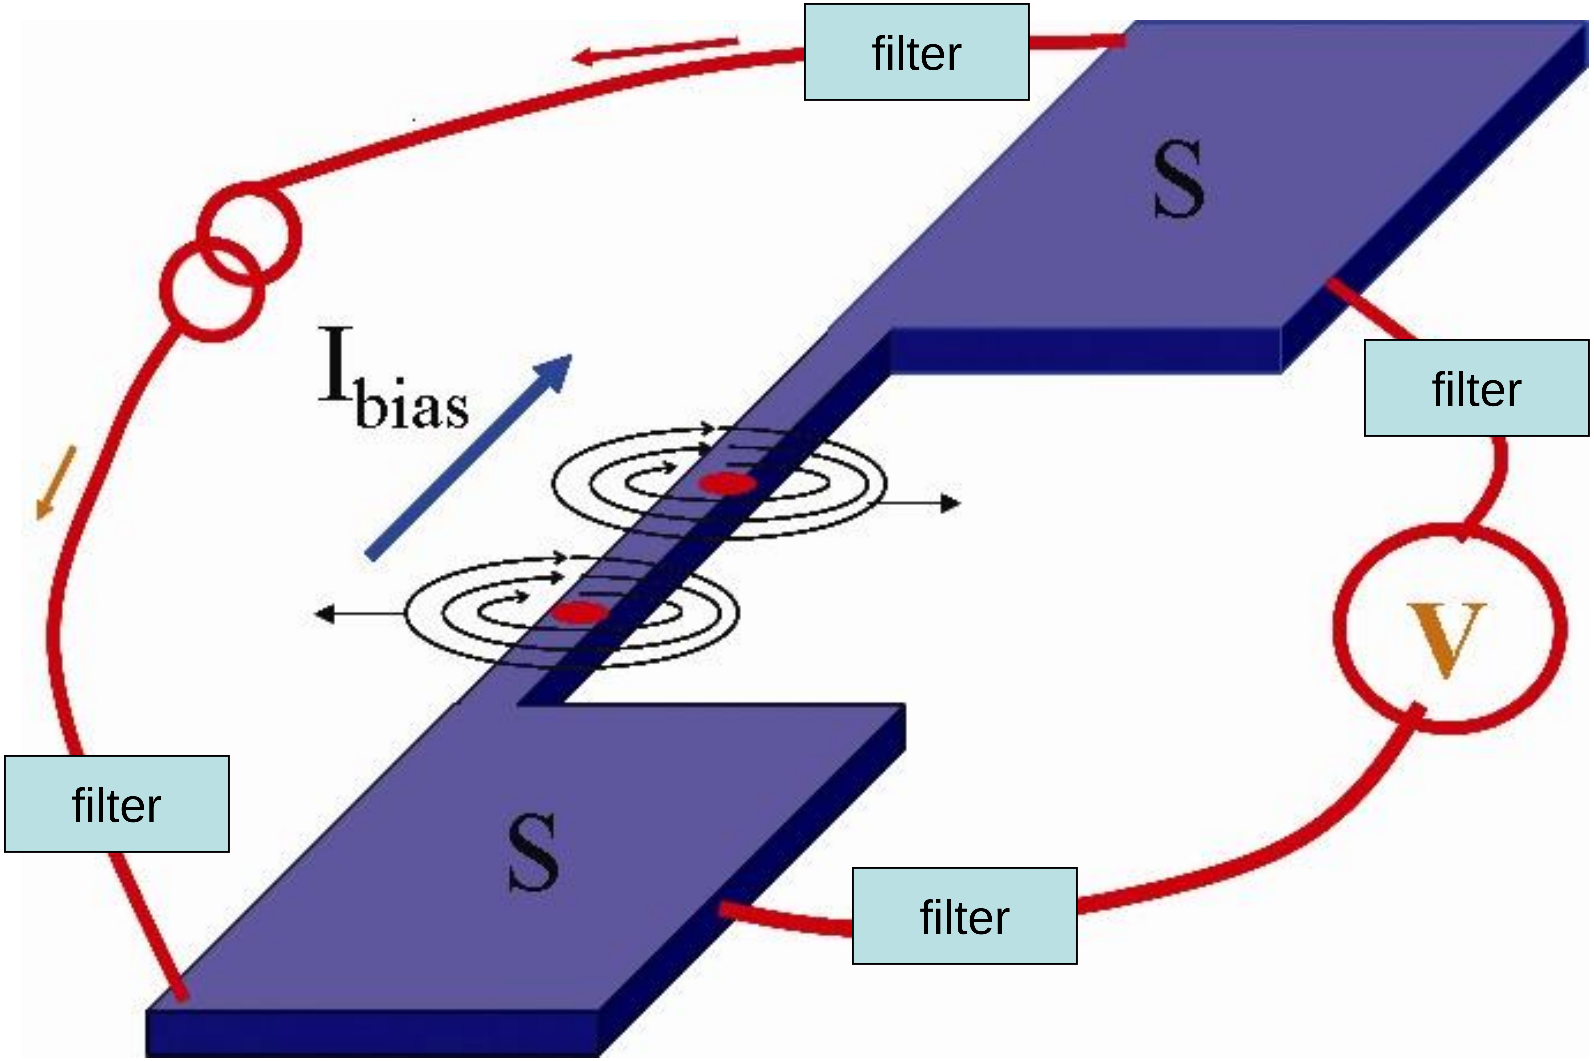
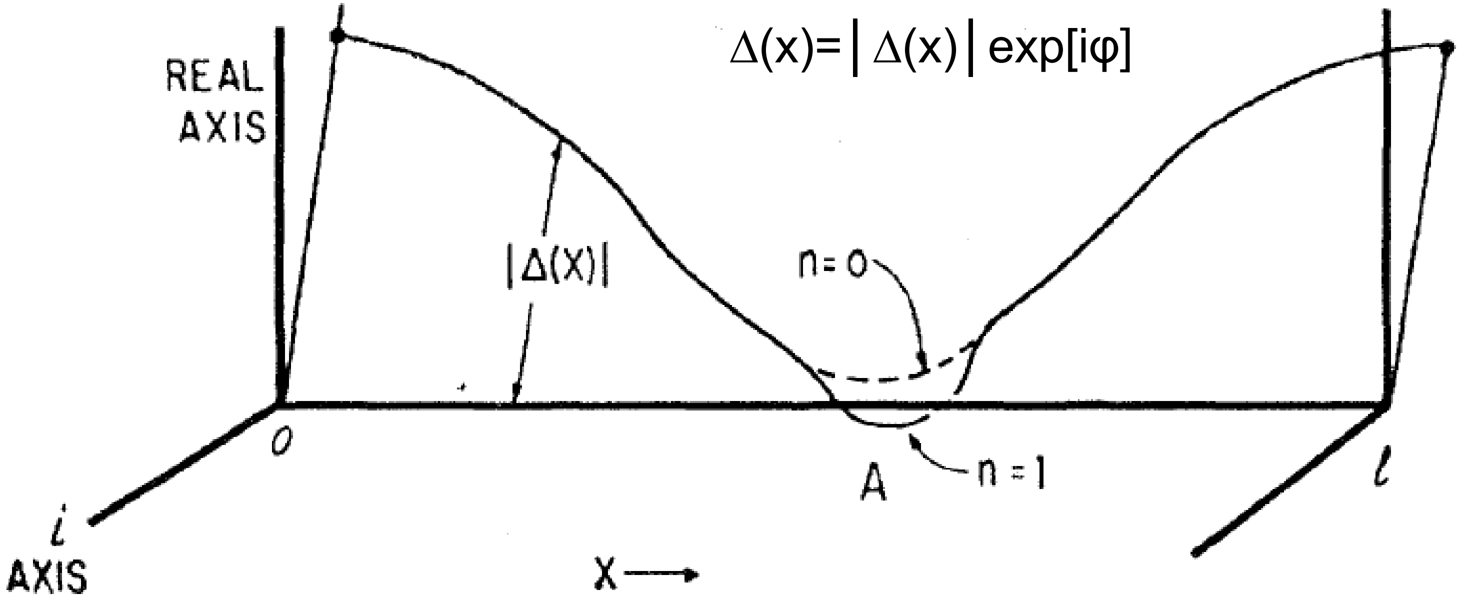
Phase slip events are shown as red dots



Transport properties: Little's Phase Slip

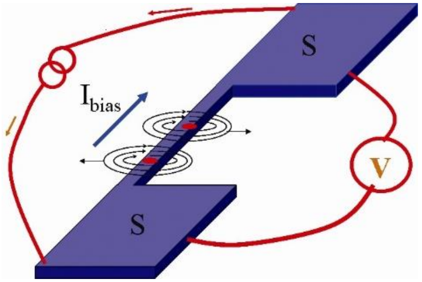


W. A. Little, "Decay of persistent currents in small superconductors", Physical Review, V.156, pp.396-403 (1967).

Two types of phase slips (PS) can be expected:

1. The usual, thermally activated PS (TAPS)
2. Quantum phase slip (QPS)

How to use voltage to determine the rate of phase slips?



Phase evolution equation: $d\varphi/dt = 2eV/\hbar$

Simplified derivation:

1. From Schrödinger equation: $i\hbar(d\Psi/dt)=E\ \Psi$
2. The solution is: $\Psi=\exp(-iEt/\hbar)$
3. The phase of the wavefunction is $\varphi=Et/\hbar$

Superconducting electrons form pairs, so the energy is: $E=2eV$

(here V is the electric potential or voltage)

The resulting phase-evolution equation is: $d\varphi/dt = 2eV/\hbar$

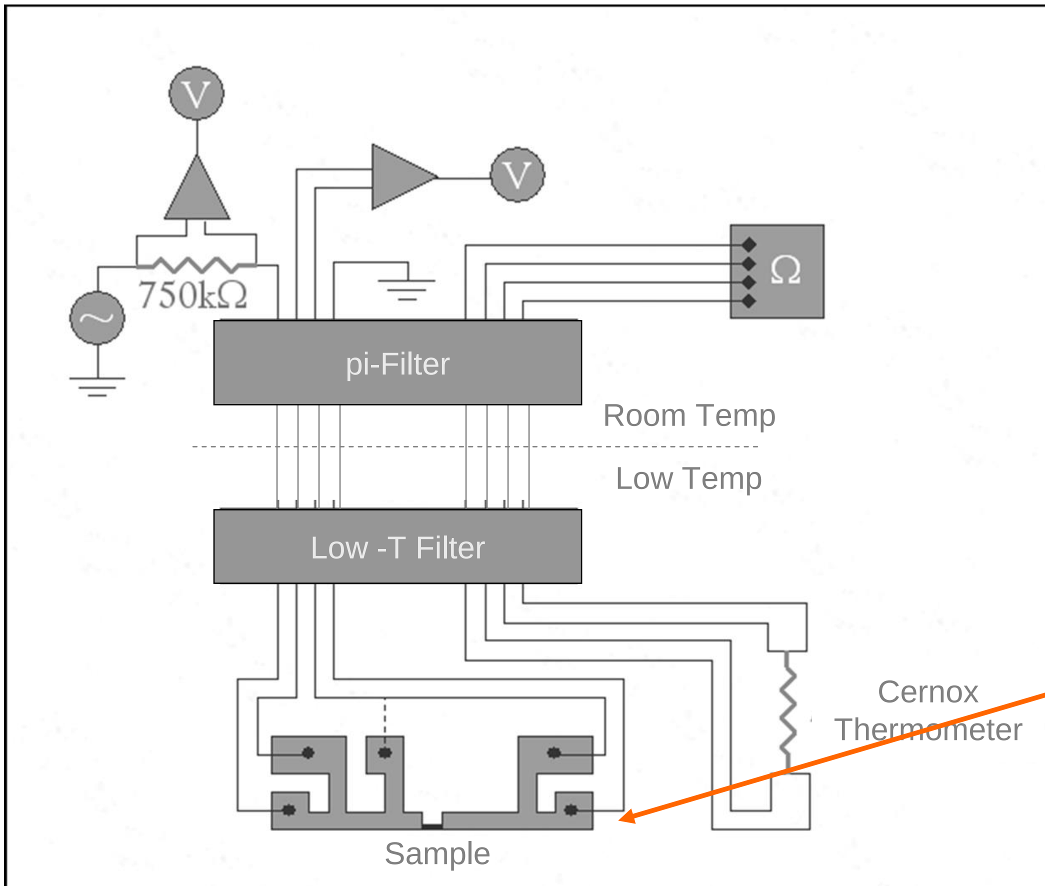
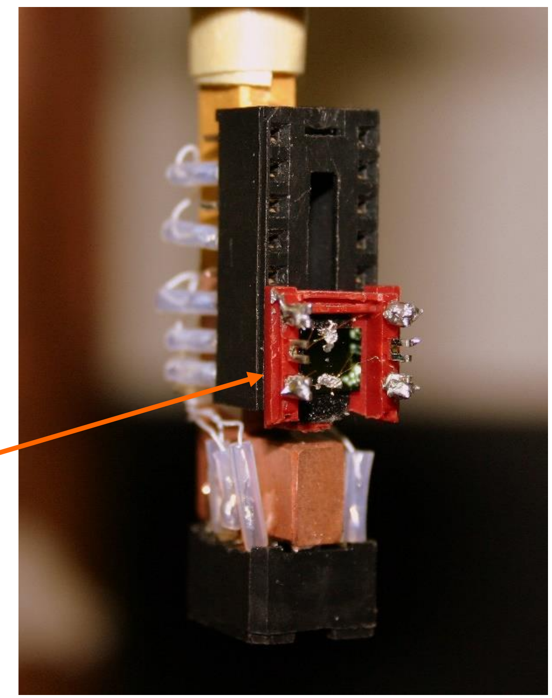
Measurement Scheme



Circuit Diagram



Sample mounted on the ^{3}He insert.

Tony Bollinger's sample-mounting procedure in winter in Urbana

Procedure (~75% Success)

- Put on gloves

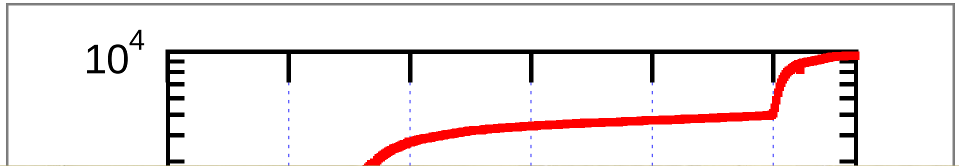
- Put grounded socket for mounting in vise with grounded indium dot tool connected
- Spray high-backed black chair all over and about 1 m square meter of ground with anti-static spray

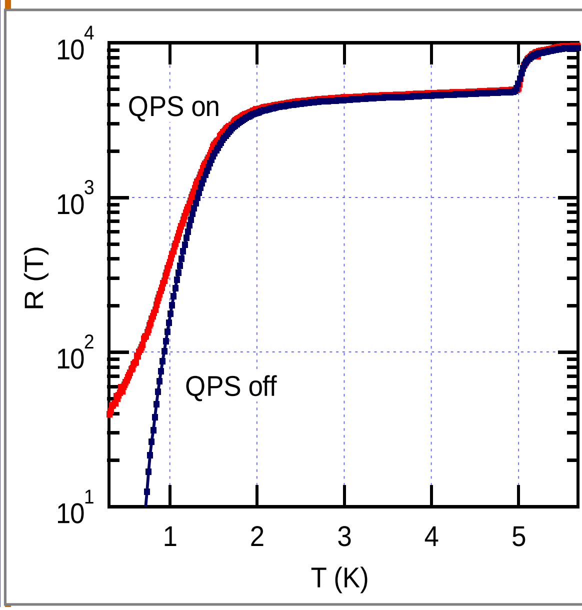
  - DO NOT use green chair
  - Not sure about short-backed black chairs

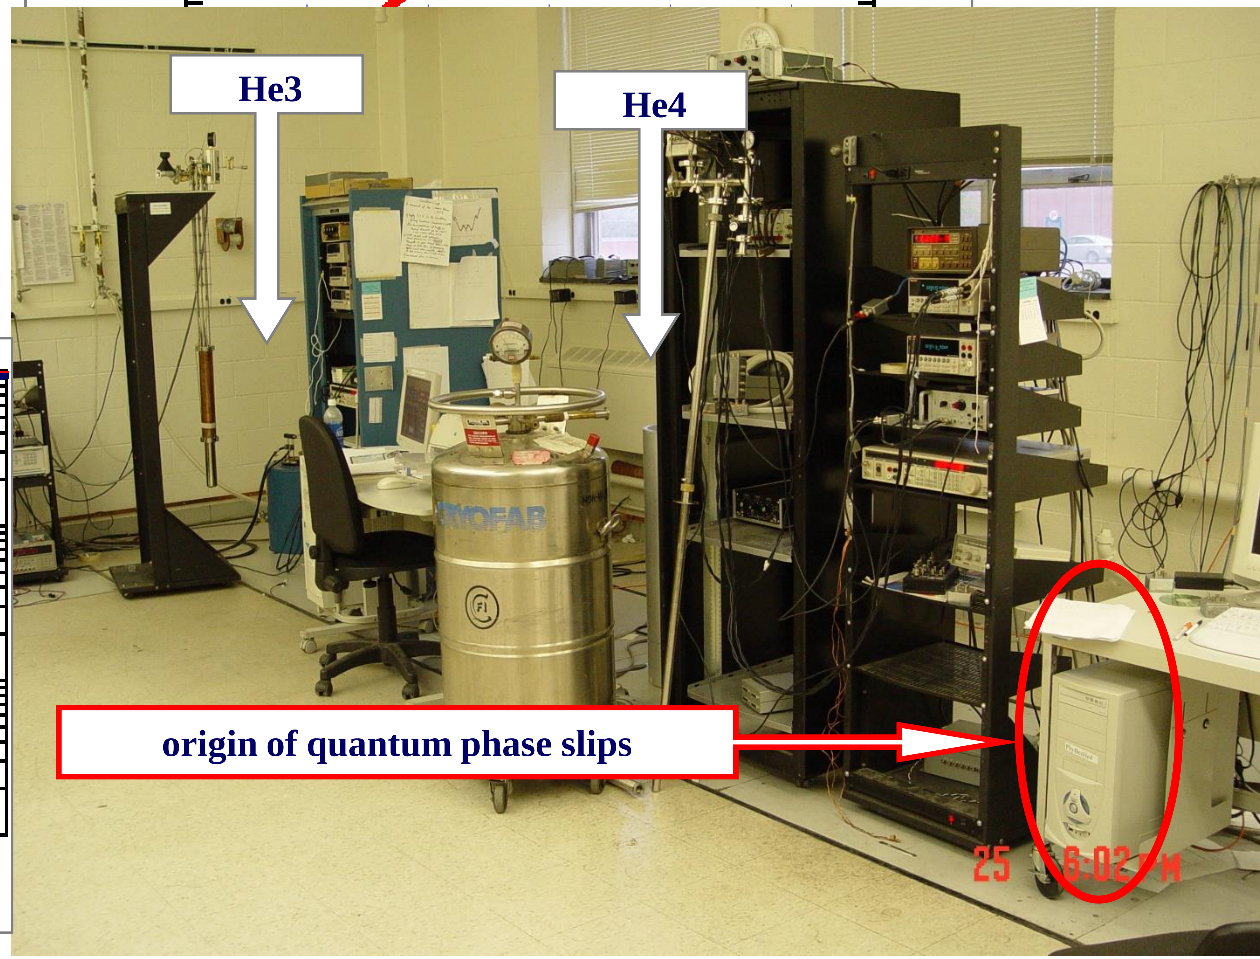
- Sit down
- Spray bottom of feet with anti-static spray

- Plant feet on the ground. ***Do not move your feet again for any reason until mounting is finished.***
- Mount sample
- Keep sample in grounded socket until last possible moment
- Test samples in dipstick at ~1 nA

Possible Origin of Quantum Phase Slips







Dichotomy in nanowires: Evidence for superconductor-insulator transition (SIT)

Quantum limit to phase coherence in thin superconducting wires

M. Tinkham[a] and C. N. Lau
Physics Department, Harvard University, Cambridge, Massachusetts 02138

Linearity of the Schrödinger's equation

Suppose Ψ_1 is a valid solution of the Schrödinger equation:

$$i\hbar\frac{\partial\psi_1}{\partial t} = \frac{\partial^2\psi_1}{\partial x^2} + U(x)\psi_1$$

And suppose that Ψ_2 is another valid solution of the Schrödinger equation:

$$i\hbar\frac{\partial\psi_2}{\partial t} = \frac{\partial^2\psi_2}{\partial x^2} + U(x)\psi_2$$

Then $(\Psi_1 + \Psi_2)/\sqrt{2}$ is also a valid solution, because:

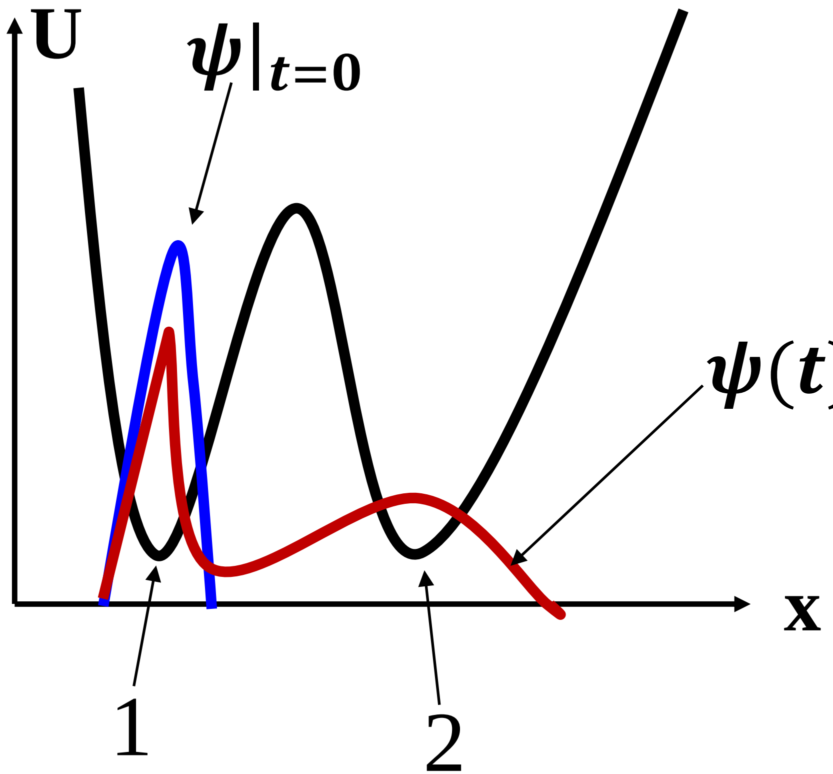
$$i\hbar\frac{\partial(\psi_1+\psi_2)}{\partial t} = \frac{\partial^2(\psi_1+\psi_2)}{\partial x^2} + U(x)(\psi_1+\psi_2)$$

The state $(\Psi_1 + \Psi_2)/\sqrt{2}$ is a new combined state which is called "quantum superposition" of state (1) and (2)

George Gamow

(He also developed Big Bang theory)

Quantum tunneling



Quantum tunneling is possible since quantum superpositions of states are possible.

Schrödinger cat –
the ultimate macroscopic quantum phenomenon

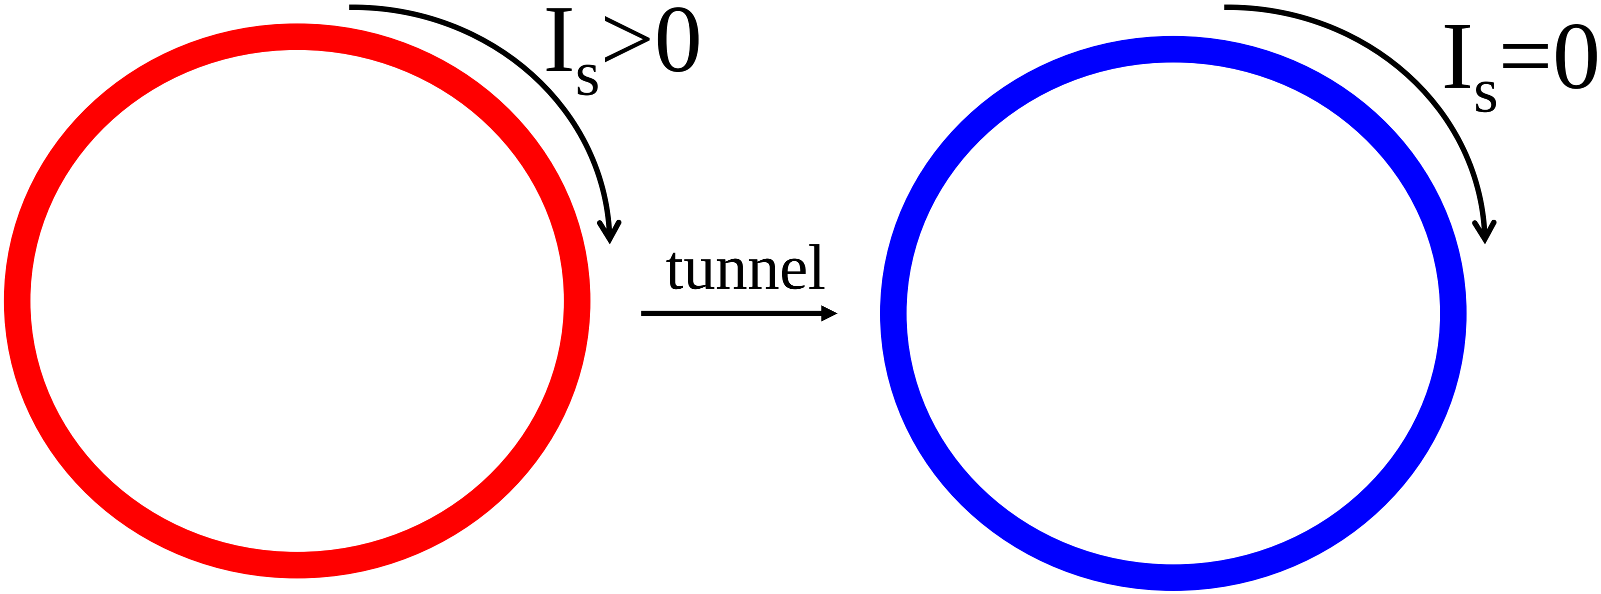
Geiger counter

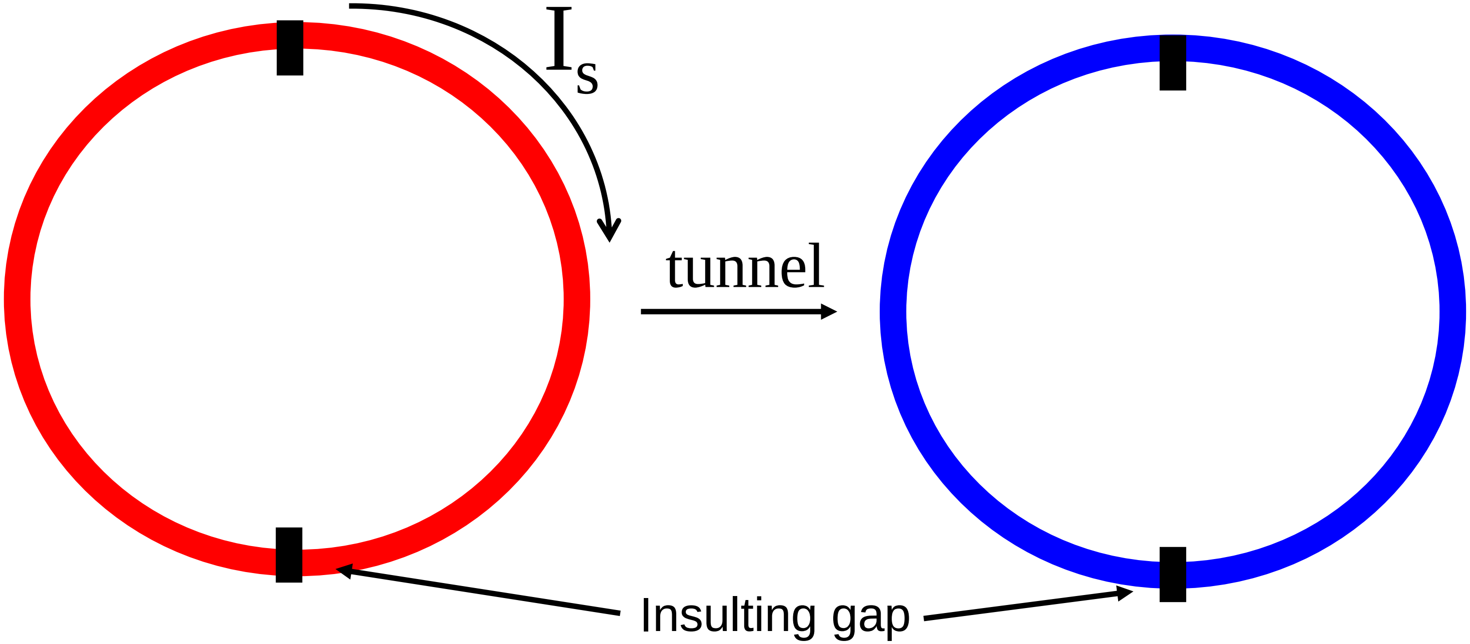
What sort of tunneling we will consider?



-Red color represents some strong current in the superconducting wire loop

-Blue color represents no current or a much smaller current in the loop

Previous results relate loops with insulating interruptions (SQUIDs)



-Red color represents some strong current in the superconducting loop

-Blue color represents no current or very little current
in the superconducting loop

Leggett's prediction for macroscopic quantum tunneling (MQT) in SQUIDs

Supplement of the Progress of Theoretical Physics, No. 69, 1980

Macroscopic Quantum Systems and the Quantum Theory of Measurement

A. J. LEGGETT

School of Mathematical and Physical Sciences
University of Sussex, Brighton BN1 9QH

(Received August 27, 1980)

It is this property which makes a SQUID the most promising candidate to date for observing macroscopic quantum tunnelling; if it should ever become possible to observe macroscopic quantum *coherence*, the low entropy and consequent lack of dissipation will be absolutely essential.[21]

MQT report by Kurkijarvi and collaborators (1981)

VOLUME 47, NUMBER 9 PHYSICAL REVIEW LETTERS 31 AUGUST 1981

Decay of the Zero-Voltage State in Small-Area, High–Current-Density Josephson Junctions

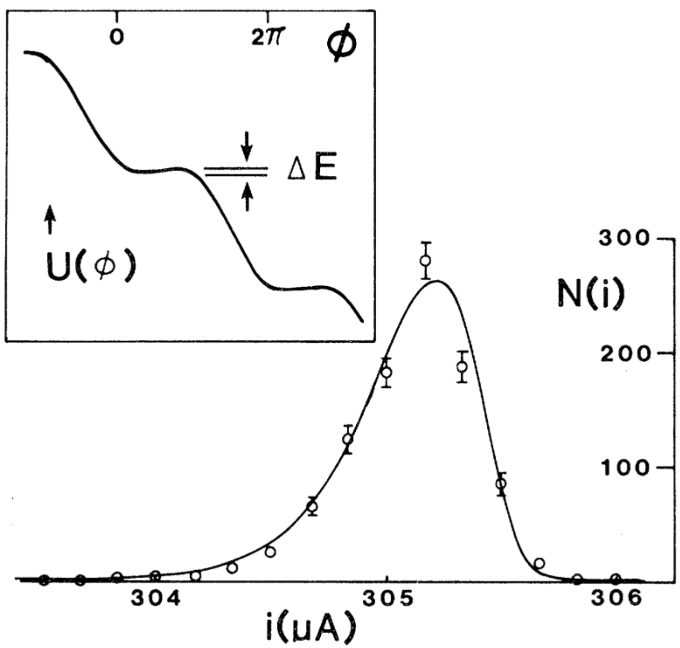


FIG. 1. Measured distribution for $T = 1.6$ K for small high–current-density junction. The solid line is a fit by the CL theory for $R = 20\ \Omega$, $C = 8$ fF, and $i_{cFF} = 310.5\ \mu$A. The inset is $U(\varphi)$ for $x = 0.8$ with barrier ΔE.

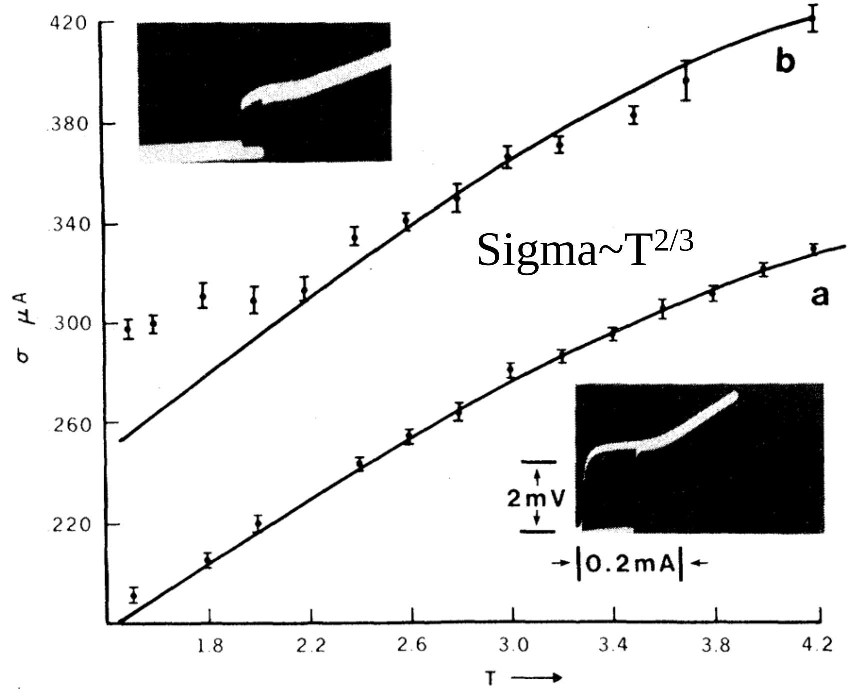

FIG. 2. Measured distribution widths σ vs T for two junctions with current sweep of ~400 μA/sec. Curve a is lower current density junction data and curve b is higher density junction data. The traces adjacent to the plots are the corresponding I–V characteristics at 4.2 K. The scales are the same for both traces.

Conclusions

- Superconductivity allows us to test some important fundamental quantum phenomena. For example, macroscopic quantum tunneling, macroscopic quantum coherence, and the quantum superposition principle, which is realized in qubits.

- Superconductivity has been used to design many types of useful devices. The examples considered are the SQUIDS and the qubits for quantum computers.
