## Mystery Code I

In line 05 the procedure MA is calling itself on a version of the input list with the kth element  $(a_k)$  removed. Assume it takes constant time to temporarily remove  $a_k$  from the list. (Doing this in constant time actually requires some extra details that we are hiding for clarity.)

```
00 MA(a_1, \ldots, a_n): list of n positive integers, n \geq 3)
          if (n = 3) return a_1 + a_2 + a_3
02
          else
03
                bestval = 0
04
                for k = 1 to n
05
                       newval = MA(a_1, a_2, ..., a_{k-1}, a_{k+1}, ... a_n)
                       if (newval > bestval) bestval = newval
06
07
                end for
08
                return bestval
```

- (a) Describe (in English) what MA computes.
- (b) Suppose that T(n) is the running time of MA on an input array of length n. Give a recursive definition of T(n).
- (c) How many leaf nodes are there in the recursion tree for T(n)? Briefly explain.
- (d) Does MA run in  $O(2^n)$  time? Briefly explain why or why not.

## Solution:

- (a) MA computes the largest sum of 3 numbers in the list.
- (b)  $T(3) = c_1$  $T(n) = n \cdot T(n-1) + c_2 n + c_3$

There loop on lines 4 - 7 runs n times and makes a recursive call each time on a list one shorter. It also does some constant work inside and outside the loop.

- (c)  $\frac{n!}{3!}$  This happens since the last level is when the list is 3 and at each level there are children equal to the length of the list. So  $n \cdot (n-1) \cdot \cdots 3$ .
- (d) Given that there are  $\Theta(n!)$  leaves even with no other work it is easy to see that it is way more than  $O(2^n)$  time.

## Mystery Code II

Consider an array of n distinct real numbers  $a_1, a_2, \ldots, a_n$ . We say that the array has a peak at position k if the following two conditions hold for every position k between 2 and k:

- (1) If  $j \le k$ , then  $a_{j-1} < a_j$ .
- (2) If j > k,  $a_{j-1} > a_j$ .

Consider the following procedure to determine position of the peak of an array (assume that the array does indeed have a peak):

```
00 procedure Find(a_1, a_2, ..., a_n): array of real numbers)
01
        if (n = 1)
02
           return 1
03
        if (a_1 > a_2)
04
           return 1
        else if (a_n > a_{n-1})
05
06
           return n
07
        k = floor((1+n)/2)
        if (a_{k-1} > a_k)
08
           return Find(a_1, \ldots, a_{k-1})
09
        else if (a_k < a_{k+1})
10
           return \operatorname{Find}(a_{k+1}, \ldots, a_n) + \mathbf{k}
11
12
        else
13
           return k
```

- (a) Consider the array -1, 3, 6, 7, 0. Trace the execution of the above pseudocode and show that it correctly returns the position of the peak.
- (b) At line 07, what is the smallest value that n might contain? Why?
- (c) Let T(n) be the worst-case running time of the above pseudocode when the array has size n. Write a recurrence for T(n), including the necessary base case(s). Assume that splitting the array (lines 09 and 11) takes constant time.
- (d) What is the tightest big-O running time of Find?

## **Solution:**

- (a) Peak([-1 3 6 7 0]) will not match any lines 1,3,5 so will compute the k=3 and then take the else if and call Peak([7 0]) which will the if at line 3 and return 1. The original function will then return 1+3=4.
- (b) 3, If n were 1, we would have returned on line 1. If n were 2, we would return on either line 4 or line 6 (because the first item is either greater than or less than the second/last). However on an input array with 3 elements whose peak is in the center, like [5, 6, 4], we can reach line 7.
- (c)  $T(1) = c_1$   $T(2) = c_2$   $T(3) = c_3$  $T(n) = T(n/2) + c_4$
- (d) If we consider the recursion tree of this code it is clear that at each level there is only one child and each node only does a constant amount of work. Thus the runtime will be simply the height of the tree. To compute this we can see that at each level the list gets smaller by one half so at most the height of the tree is  $O(\log n)$ .
