Brad Solomon

Department of Computer Science

## Learning Objectives

Formalize the concept of randomized algorithms

Review fundamentals of probability in computing

Distinguish the three main types of 'random'in computer science

## Randomized Algorithms

A randomized algorithm is one which uses a source of randomness somewhere in its implementation.

Figure from Ondov et al 2016

$$
\begin{array}{lllllllllll}
H(x) & 0 & 2 & 1 & 0 & 0 & 4 & 0 & 2 & 0 & 6 \\
H(y) & 1 & 0 & 2 & 3 & 1 & 0 & 3 & 4 & 0 & 1 \\
H(z) & 2 & 1 & 0 & 2 & 0 & 1 & 0 & 0 & 7 & 2
\end{array}
$$

## A faulty list

Imagine you have a list ADT implementation except...
Every time you called insert, it would fail $50 \%$ of the time.

## Quick Primes with Fermat's Primality Test

If $p$ is prime and $a$ is not divisible by $p$, then $a^{p-1} \equiv 1(\bmod p)$
But... sometimes if $n$ is composite and $a^{n-1} \equiv 1(\bmod n)$

## Fundamentals of Probability

Imagine you roll a pair of six-sided dice.
The sample space $\Omega$ is the set of all possible outcomes.

An event $E \subseteq \Omega$ is any subset.

## Fundamentals of Probability

Imagine you roll a pair of six-sided dice. What is the expected value?
A random variable is a function from events to numeric values.

The expectation of a (discrete) random variable is:

$$
E[X]=\sum_{x \in \Omega} \operatorname{Pr}\{X=x\} \cdot x
$$

## Fundamentals of Probability

Imagine you roll a pair of six-sided dice. What is the expected value?
Linearity of Expectation: For any two random variables $X$ and $Y$,
$E[X+Y]=E[X]+E[Y]$

## Fundamentals of Probability

Imagine you roll a pair of six-sided dice. What is the expected value?
Linearity of Expectation: For any two random variables $X$ and $Y$,
$E[X+Y]=E[X]+E[Y]$

$$
\begin{aligned}
& =\sum_{x} \sum_{y} \operatorname{Pr}\{X=x, Y=y\}(x+y) \\
& =\sum_{x} x \sum_{y} \operatorname{Pr}\{X=x, Y=y\}+\sum_{y} y \sum_{x} \operatorname{Pr}\{X=x, Y=y\} \\
& =\sum_{x} x \cdot \operatorname{Pr}\{X=x\}+\sum_{y} y \cdot \operatorname{Pr}\{Y=y\}
\end{aligned}
$$

## Fundamentals of Probability

Imagine you roll a pair of six-sided dice. What is the expected value?
Linearity of Expectation: For any two random variables $X$ and $Y$,
$E[X+Y]=E[X]+E[Y]$

## Randomization in Algorithms

1. Assume input data is random to estimate average-case performance
2. Use randomness inside algorithm to estimate expected running time
3. Use randomness inside algorithm to approximate solution in fixed time

Average-Case Analysis: BST

Smallest

Largest

## Average-Case Analysis: BST

Let $S(n)$ be the average total internal path length over all BSTs that can be constructed by uniform random insertion of $n$ objects

Claim: $S(n)$ is $O(n \log n)$
$\mathbf{N}=0: \quad \mathbf{N}=1:$

## Average-Case Analysis: BST

Let $S(n)$ be the average total internal path length over all BSTs that can be constructed by uniform random insertion of $n$ objects
$\mathrm{N}=3$ :

## Average-Case Analysis: BST

Let $S(n)$ be the average total internal path length over all BSTs that can be constructed by uniform random insertion of $n$ objects Let $0 \leq i \leq n-1$ be the number of nodes in the left subtree.

Then for a fixed $i, S(n)=(n-1)+S(i)+S(n-i-1)$

## Average-Case Analysis: BST

Let $S(n)$ be the average total internal path length over all BSTs that can be constructed by uniform random insertion of $n$ objects

$$
S(n)=(n-1)+\frac{1}{n} \sum_{i=0}^{n-1} S(i)+S(n-i-1)
$$

Average-Case Analysis: BST

$$
\begin{aligned}
& S(n)=(n-1)+\frac{2}{n} \sum_{i=1}^{n-1} S(i) \\
& S(n)=(n-1)+\frac{2}{n} \sum_{i=1}^{n-1}(c i \ln i) \\
& S(n) \leq(n-1)+\frac{2}{n} \int_{1}^{n}(c x \ln x) d x \\
& S(n) \leq(n-1)+\frac{2}{n}\left(\frac{c n^{2}}{2} \ln n-\frac{c n^{2}}{4}+\frac{c}{4}\right) \approx c n \ln n
\end{aligned}
$$

## Average-Case Analysis: BST

Let $S(n)$ be the average total internal path length over all BSTs that can be constructed by uniform random insertion of $n$ objects

Since $S(n)$ is $O(n \log n)$, if we assume we are randomly choosing a node to insert, find, or delete* then each operation takes:

## Average-Case Analysis: BST

Summary: All operations are on average $O(\log n)$

Randomness:

Assumptions:

Expectation Analysis: Randomized Quicksort

| 6 | 1 | 0 | 3 | 7 | 9 | 2 | 4 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 1 | 0 | 3 | 2 | 4 | 9 | 6 | 7 |
| 1 | 0 | 3 | 2 | 4 | 9 | 6 | 7 |
| 1 | 0 | 2 | 3 | 4 | 6 | 7 | 7 |
| 1 | 0 | 2 | 3 | 4 | 4 | 6 | 7 |
| 0 | 1 | 2 | 3 | 4 | 6 |  |  |

Expectation Analysis: Randomized Quicksort

| 6 | 1 | 0 | 3 |  | 79 |  | 2 |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Expectation Analysis: Randomized Quicksort

In randomized quicksort, the selection of the pivot is random.
Claim: The expected time is $O(n \log n)$ for any input!
Let $X$ be the total comparisons and $X_{i j}$ be an indicator variable:
$X_{i j}=\left\{\begin{array}{l}1 \text { if } i \text { th object compared to } j \text { th } \\ 0 \text { if } i \text { th object not compared to } j \text { th }\end{array}\right.$
Then...

## Expectation Analysis: Randomized Quicksort

Claim: $E\left[X_{i, j}\right]=\frac{2}{j-i+1}$.
Base Case: ( $\mathrm{N}=2$ )

## Expectation Analysis: Randomized Quicksort

Claim: $E\left[X_{i, j}\right]=\frac{2}{j-i+1} \quad$ Induction: Assume true for all inputs of $<n$

Expectation Analysis: Randomized Quicksort

$$
E[X]=\sum_{i=1}^{n} \sum_{j=i+1}^{n} E\left[X_{i j}\right] \quad E\left[X_{i j}\right]=\frac{2}{j-i+1}
$$

Expectation Analysis: Randomized Quicksort

$$
\begin{aligned}
& E[X]=\sum_{i=1}^{n} \sum_{j=i+1}^{n} E\left[X_{i j}\right] \quad E\left[X_{i j}\right]=\frac{2}{j-i+1} \\
& E[X]=\sum_{i=1}^{n} 2\left(\frac{1}{2}+\frac{1}{3}+\ldots+\frac{1}{n-i+1}\right) \\
& E[X]=\sum_{i=1}^{n} 2\left(H_{n-1}-1\right) \leq 2 n \cdot H_{n} \leq 2 n \ln n
\end{aligned}
$$

## Expectation Analysis: Randomized Quicksort

Summary: Randomized quick sort is $O(n \log n)$ regardless of input

Randomness:

Assumptions:

## Probabilistic Accuracy: Fermat primality test

Pick a random $a$ in the range [2, $p-2$ ]
If $p$ is prime and $a$ is not divisible by $p$, then $a^{p-1} \equiv 1(\bmod p)$
But... sometimes if $n$ is composite and $a^{n-1} \equiv 1(\bmod n)$

## Probabilistic Accuracy: Fermat primality test

|  | $a^{p-1} \equiv 1(\bmod p)$ | $a^{p-1} \not \equiv 1(\bmod p)$ |
| :--- | :--- | :--- |
| $p$ is prime |  |  |
| $p$ is not prime |  |  |
|  |  |  |

## Probabilistic Accuracy: Fermat primality test

Let's assume $\alpha=.5$
First trial: $a=a_{0}$ and prime test returns 'prime!'
Second trial: $a=a_{1}$ and prime test returns 'prime!'
Third trial: $a=a_{2}$ and prime test returns 'not prime!'
Is our number prime?

What is our false positive probability? Our false negative probability?

## Probabilistic Accuracy: Fermat primality test

Summary: Randomized algorithms can also have fixed (or bounded) runtimes at the cost of probabilistic accuracy.

Randomness:

Assumptions:

## Types of randomized algorithms

A Las Vegas algorithm is a randomized algorithm which will always give correct answer if run enough times but has no fixed runtime.

A Monte Carlo algorithm is a randomized algorithm which will run a fixed number of iterations and may give the correct answer.

## Next Class: Randomized Data Structures

Sometimes a data structure can be too ordered / too structured

Randomized data structures rely on expected performance

Randomized data structures 'cheat' tradeoffs!
