- **1** Suppose we are given an array A[1..n] of n distinct integers, which could be positive, negative, or zero, sorted in increasing order so that  $A[1] < A[2] < \cdots < A[n]$ .
  - **1.A.** Describe a fast algorithm that either computes an index i such that A[i] = i or correctly reports that no such index exists.
  - **1.B.** Suppose we know in advance that A[1] > 0. Describe an even faster algorithm that either computes an index *i* such that A[i] = i or correctly reports that no such index exists. (Hint: This is really easy.)
- 2 Suppose we are given an array A[1..n] such that  $A[1] \ge A[2]$  and  $A[n-1] \le A[n]$ . We say that an element A[x] is a **local minimum** if both  $A[x-1] \ge A[x]$  and  $A[x] \le A[x+1]$ . For example, there are exactly six local minima in the following array:

Describe and analyze a fast algorithm that returns the index of one local minimum. For example, given the array above, your algorithm could return the integer 9, because A[9] is a local minimum. (Hint: With the given boundary conditions, any array **must** contain at least one local minimum. Why?)

3 Suppose you are given two sorted arrays A[1..n] and B[1..n] containing distinct integers. Describe a fast algorithm to find the median (meaning the *n*th smallest element) of the union  $A \cup B$ . For example, given the input

A[1..8] = [0, 1, 6, 9, 12, 13, 18, 20] B[1..8] = [2, 4, 5, 8, 17, 19, 21, 23]

your algorithm should return the integer 9. (Hint: What can you learn by comparing one element of A with one element of B?)

## To think about later:

4 Now suppose you are given two sorted arrays A[1..m] and B[1..n] and an integer k. Describe a fast algorithm to find the kth smallest element in the union  $A \cup B$ . For example, given the input

A[1..8] = [0, 1, 6, 9, 12, 13, 18, 20] B[1..5] = [2, 5, 7, 17, 19] k = 6

your algorithm should return the integer 7.
