

Resources and Blocking

Priority Inheritance Priority Ceiling Stack Resource Policy

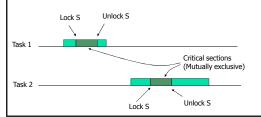

The Problem

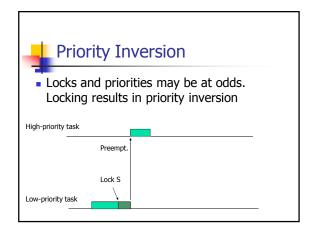

- Tasks have synchronization constraints
 - Semaphores protect critical sections
- Blocking can cause a higher-priority task to wait on a lower-priority one to unlock a resource
 - Problem: In all previous derivations we assumed that a task can only wait for higher-priority tasks not lower-priority tasks
- Question
 - What is the maximum amount of time a higher-priority task can wait for a lower-priority task?
 - How to account for that time in schedulability analysis?

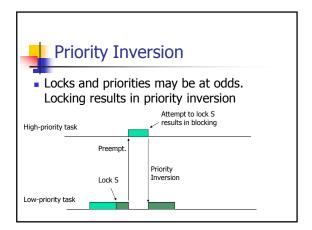

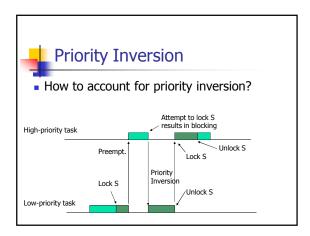

Mutual Exclusion Constraints

 Tasks that lock/unlock the same semaphore are said to have a mutual exclusion constraint

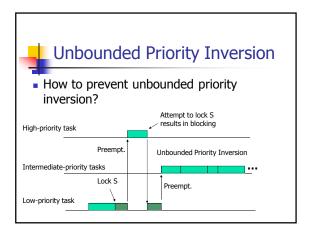

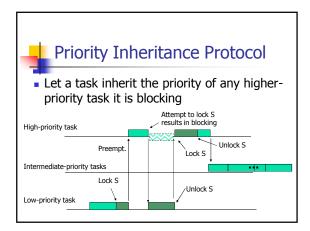

Priority Inheritance Protocol

- Question: What is the longest time a task can wait for lower-priority tasks?
 - Let there be N tasks and M semaphores
 - \blacksquare Let the largest critical section of task i be of length B_i
- Answer: ?

Computing the Maximum Priority Inversion Time

- Consider the instant when a high-priority task that arrives.
 - What is the most it can wait for lower priority ones?

Semanhore Oueus

emaphore Queue

Resource M If I am a task, priority inversion occurs when (a) Lower priority task holds a resource I need (direct blocking) (b) Lower priority task inherits a higher priority than me because it holds a resource the higher-priority task needs (push-through blocking)

Maximum Blocking Time

- When there are no nested semaphores
 - If all critical sections are equal (of length *B*):
 - Blocking time = B min (N, M) (Why?)
 - If they are not equal?

Maximum Blocking Time

- If all critical sections are equal (of length *B*):
 - Blocking time = B min (N, M) (Why?)
- If they are not equal
 - Find the worst (maximum length) critical section for each resource
 - Add up the top min (N, M) sections in size
- The total priority inversion time for task i is called B_i

Schedulability Test

$$\forall i, 1 \le i \le n,$$

$$\frac{B_i}{P_i} + \sum_{k=1}^{i} \frac{C_k}{P_k} \le i(2^{1/i} - 1)$$

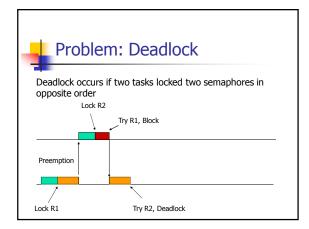

Schedulability Test

$$\forall i, 1 \le i \le n,$$

$$\frac{B_i}{P_i} + \sum_{k=1}^{i} \frac{C_k}{P_k} \le i(2^{1/i} - 1)$$

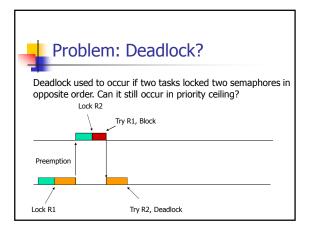

Why do we have to test each task separately? Why not just one utilization-based test like it used to?

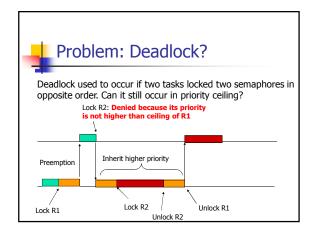

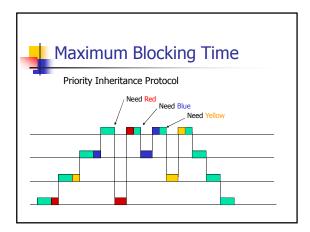

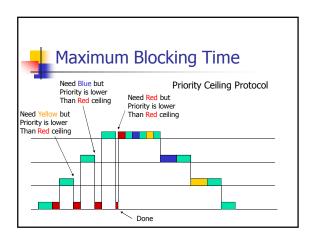

Priority Ceiling Protocol

- Definition: The priority ceiling of a semaphore is the highest priority of any task that can lock it
- A task that requests a lock R_k is denied if its priority is not higher than the highest priority ceiling of all currently locked semaphores (say it belongs to semaphore R_b)
 - \bullet The task is said to be blocked by the task holding lock R_{h}
- A task inherits the priority of the top higherpriority task it is blocking

Schedulability

 A task can be preempted by only one critical section of a lower priority task (that is guarded by a semaphore of equal or higher priority ceiling). Let max length of such section be B_i

$$\forall i, 1 \le i \le n,$$

$$\frac{B_i}{P_i} + \sum_{k=1}^{i} \frac{C_k}{P_k} \le i(2^{1/i} - 1)$$

Stack Resource Policy

- Priority:
- Any static or dynamic policy (e.g., EDF, RM, ...)
- Preemption Level
 - Any fixed value that satisfies: If A arrives after B and Priority (A) > Priority (B) then PreemptionLevel (A) > PreemptionLevel (B)
- Resource Ceiling
 - Highest preemption level of all tasks that might access the resource
- System Ceiling
 - Highest resource ceiling of all currently locked resources
- A task can preempt another if:
 - It has the highest priority
 - Its preemption level is higher than the system ceiling

Example: EDF

- Priority is proportional to the absolute deadline
- Preemption level is proportional to the relative deadline.
- Observe that:
 - If A arrives after B and Priority (A) > Priority (B) then PreemptionLevel (A) > PreemptionLevel (B)
