Lecture 4

Failure Detection

Reading: Section 15.1 and parts of 2.4.2

Next Week

- **Next Tuesday: Jack Dorsey**, co-founder of Twitter and founder of Square (mobile payments) is visiting our class 2-2.30pm!
- Townhall-style Q&A
- We are using Google Moderator to post questions, and up/down-vote questions
- Please follow the Google Moderator link from the website – vote and post your own questions!

Your new datacenter

- **You've been put in charge of a datacenter (think of the Prineville Facebook DC), and your manager has told you, "Oh no! We don't have any failures in our datacenter!"**
- **Do you believe him/her?**
- **What would be your first responsibility?**
- **Build a failure detector**
- **What are some things that could go wrong if you didn't do this?**

Failures are the norm

... not the exception, in datacenters.

Say, the rate of failure of one machine (OS/disk/motherboard/network, etc.) is once every 10 years (120 months) on average.

When you have 120 servers in the DC, the **mean time to failure (MTTF) of the next machine is 1 month.**

When you have 12,000 servers in the DC, the MTTF is about once every 7.2 hours!

To build a failure detector

- **You have a few options**
 1. **Hire 1000 people, each to monitor one machine in the datacenter and report to you when it fails.**
 2. **Write a failure detector program (distributed) that automatically detects failures and reports to your workstation.**

Which is more preferable, and why?

Two Different System Models

Whenever someone gives you a distributed computing problem, the first question you want to ask is, “What is the system model under which I need to solve the problem?”

❑ Synchronous Distributed System

- ❑ Each message is received within bounded time**
- ❑ Each step in a process takes $lb < \text{time} < ub$**
- ❑ (Each local clock's drift has a known bound)**

Examples: Multiprocessor systems

❑ Asynchronous Distributed System

- ❑ No bounds on message transmission delays**
- ❑ No bounds on process execution**
- ❑ (The drift of a clock is arbitrary)**

Examples: Internet, wireless networks, datacenters, most real systems

Failure Model

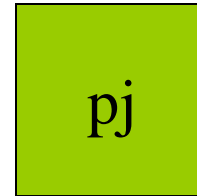

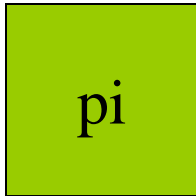

❖ Process omission failure

- ❖ Crash-stop (fail-stop) – a process halts and does not execute any further operations**
- ❖ Crash-recovery – a process halts, but then recovers (reboots) after a while**
 - ❖ Special case of crash-stop model (use a new identifier on recovery)**

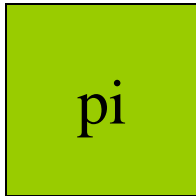

❖ We will focus on *Crash-stop* failures

- ❖ They are easy to detect in synchronous systems**
- ❖ Not so easy in asynchronous systems**

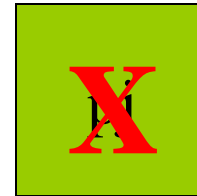

What's a failure detector?

What's a failure detector?

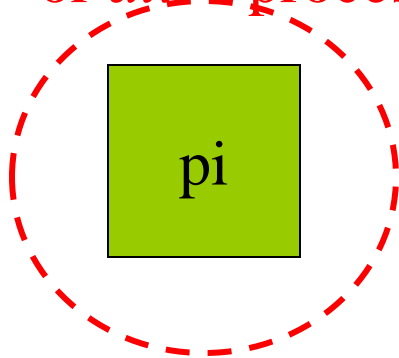

Crash-stop failure
(p_j is a *failed* process)

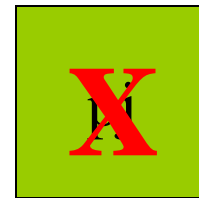

What's a failure detector?

needs to know about p_j 's failure
(p_i is a *non-faulty* process
or *alive* process)

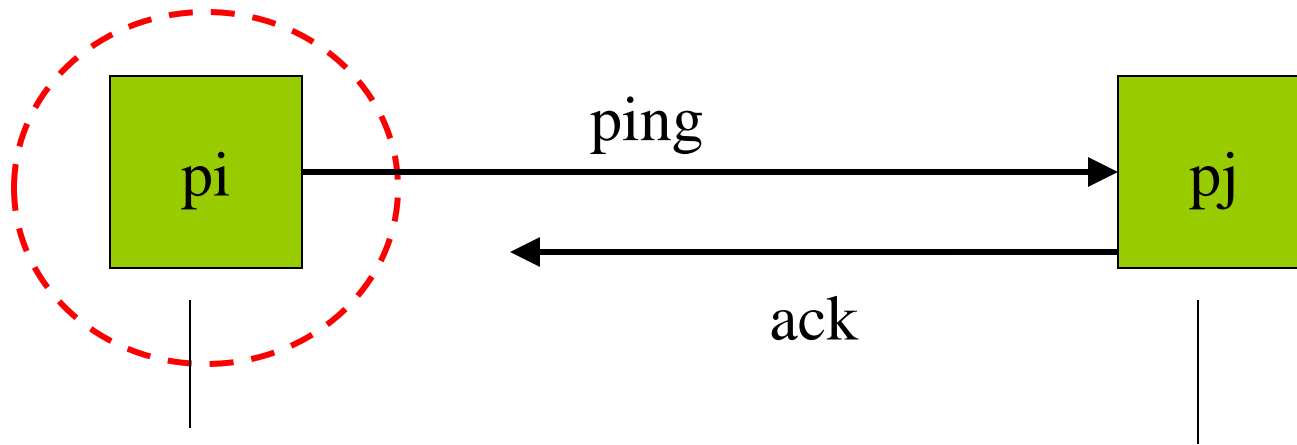

Crash-stop failure
(p_j is a *failed* process)

There are two main flavors of Failure Detectors...

I. Ping-Ack Protocol

needs to know about p_j 's failure

- p_i queries p_j once every T time units
- p_j replies
- if p_j does not respond within another T time units of being sent the ping, p_i detects p_j as failed

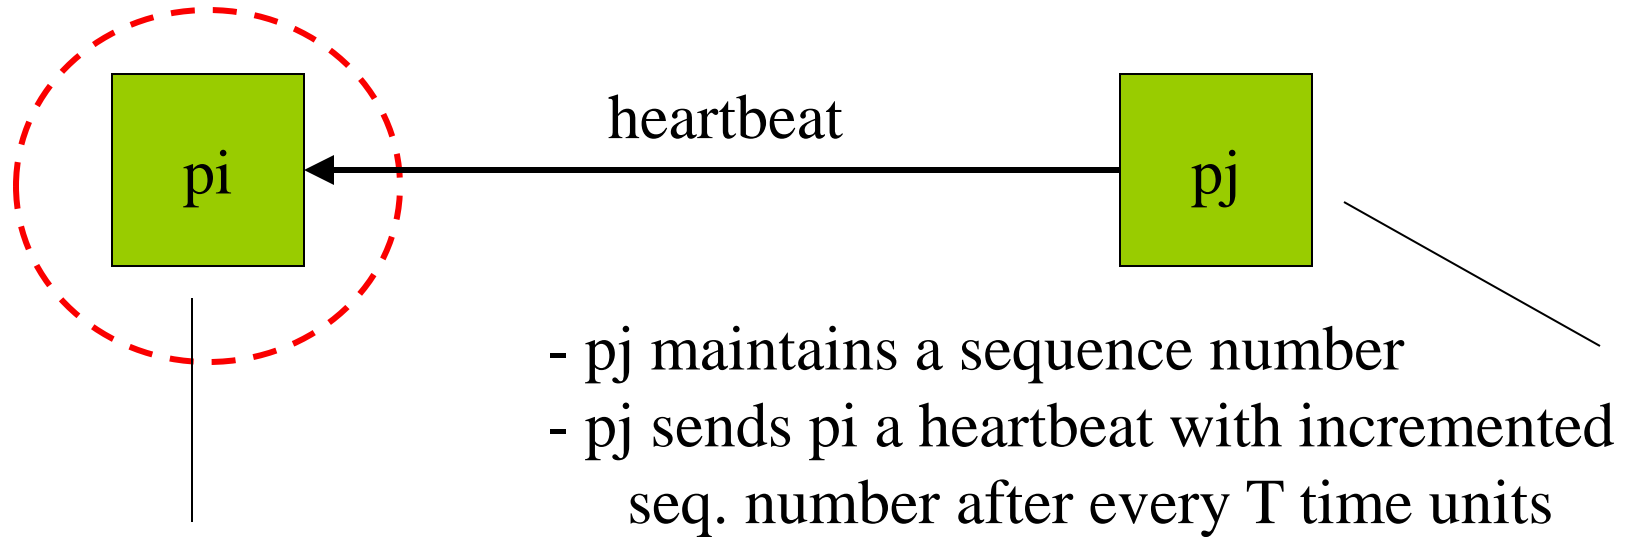

Worst case Detection time = $2T$

If p_j fails, then within T time units, p_i will send it a ping message. p_i will time out within another T time units.

The waiting time ' T ' can be parameterized.

II. Heartbeating Protocol

needs to know about p_j 's failure

-if p_i has not received a new heartbeat for the past, say $3 \cdot T$ time units, since it received the last heartbeat, then p_i detects p_j as failed

If $T \gg$ round trip time of messages, then worst case detection time $\sim 3 \cdot T$ (why?)

The '3' can be changed to any positive number since it is a parameter

In a Synchronous System

- **The Ping-ack and Heartbeat failure detectors are always correct**
 - If a process p_j fails, then p_i will detect its failure as long as p_i itself is alive
- **Why?**
 - Ping-ack: set waiting time ' T ' to be $>$ round—trip time upper bound
 - » $p_i \rightarrow p_j$ latency + p_j processing + $p_j \rightarrow p_i$ latency + p_i processing time
 - Heartbeat: set waiting time ' $3 \cdot T$ ' to be $>$ round—trip time upper bound

Failure Detector Properties

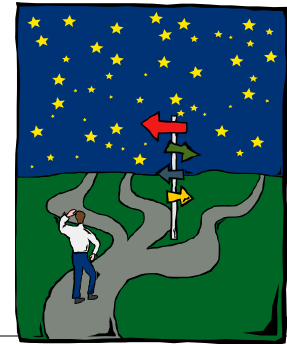

- **Completeness** = every process failure is eventually detected (no misses)
- **Accuracy** = every detected failure corresponds to a crashed process (no mistakes)
- What is a protocol that is 100% complete?
- What is a protocol that is 100% accurate?
- **Completeness and Accuracy**
 - Can both be guaranteed 100% in a synchronous distributed system
 - Can never be guaranteed simultaneously in an asynchronous distributed system

Why?

Satisfying both Completeness and Accuracy in Asynchronous Systems

- **Impossible because of arbitrary message delays, message losses**
 - If a heartbeat/ack is dropped (or several are dropped) from p_j , then p_j will be mistakenly detected as failed => inaccurate detection
 - How large would the T waiting period in ping-ack or $3 \cdot T$ waiting period in heartbeating, need to be to obtain 100% accuracy?
 - **In asynchronous systems, delay/losses on a network link are impossible to distinguish from a faulty process**
- **Heartbeating – satisfies completeness but not accuracy (why?)**
- **Ping-Ack – satisfies completeness but not accuracy (why?)**

Completeness or Accuracy? (in asynchronous system)

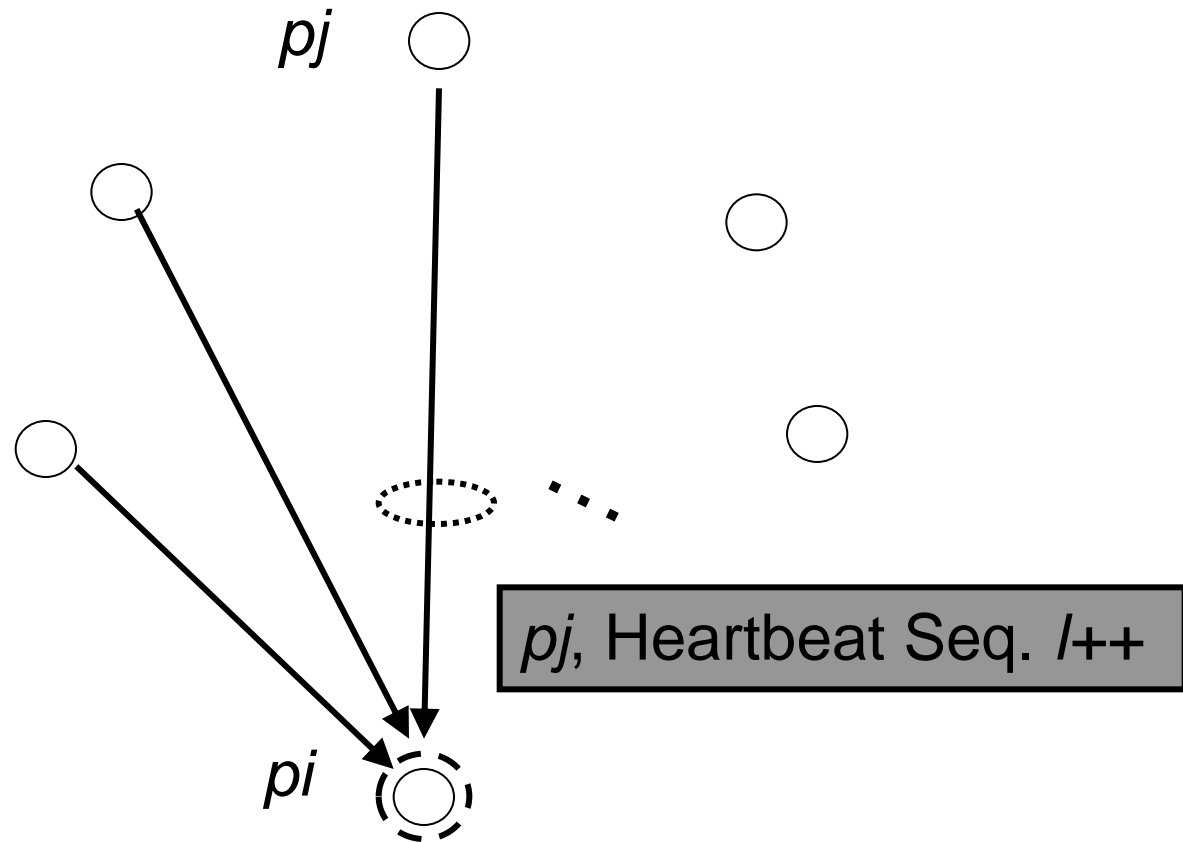

- Most failure detector implementations are willing to tolerate some inaccuracy, but require 100% Completeness
- Plenty of distributed apps designed assuming 100% completeness, e.g., p2p systems
 - “Err on the side of caution”.
 - Processes not “stuck” waiting for other processes
- But it’s ok to mistakenly detect once in a while since – the victim process need only rejoin as a new process and catch up
- Both Hearbeating and Ping-ack provide
 - *Probabilistic* accuracy: for a process detected as failed, with some probability close to 1.0 (but not equal), it is true that it has actually crashed.

Failure Detection in a Distributed System

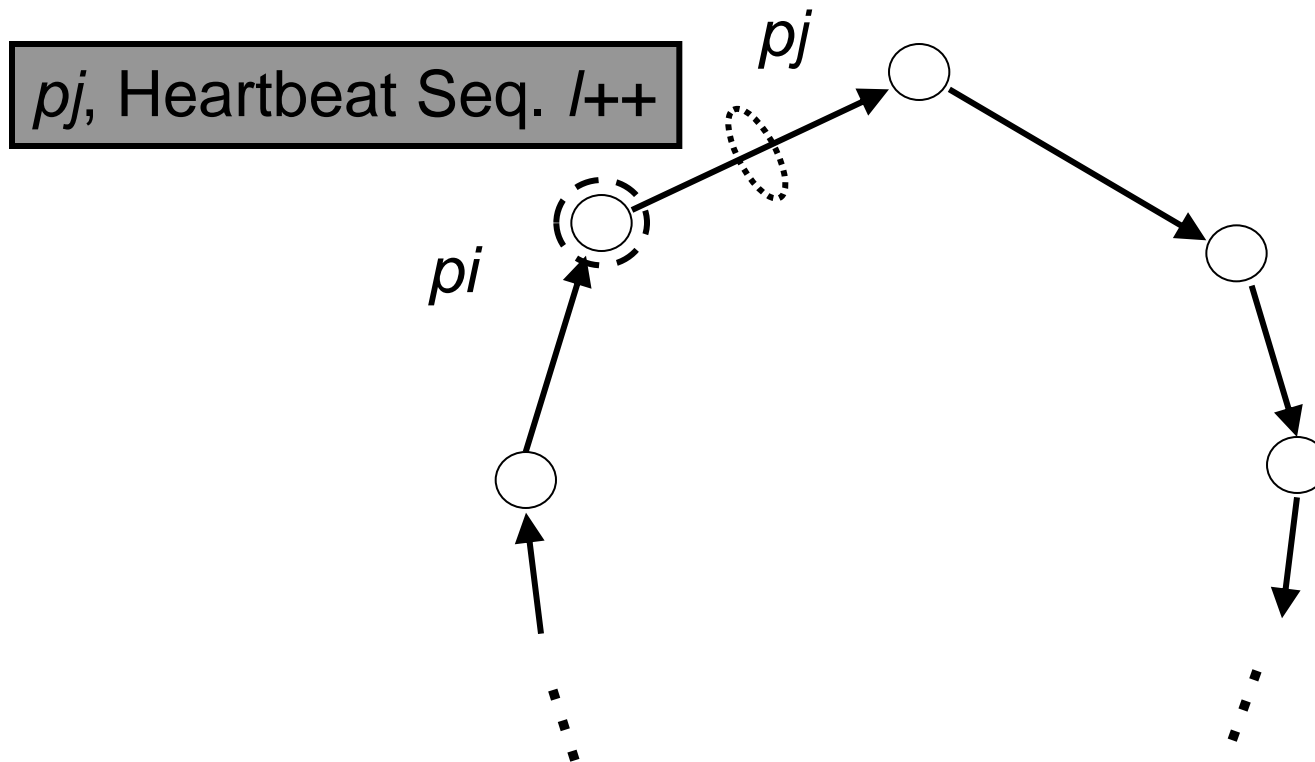

- That was for one process p_j being detected and one process p_i detecting failures
- Let's extend it to an entire distributed system
- Difference from original failure detection is
 - We want failure detection of not merely one process (p_j), but *all* processes in system

Centralized Heartbeating

Downside?

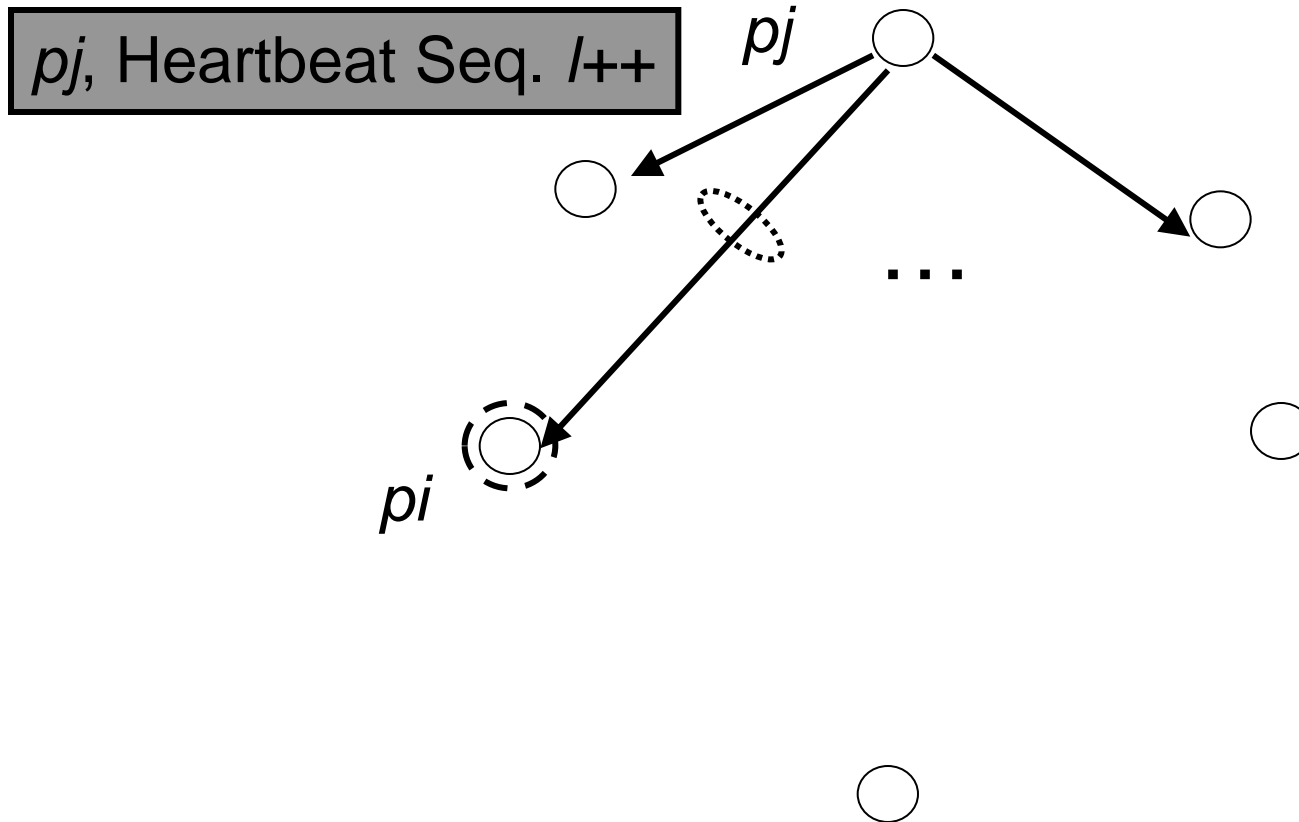

Ring Heartbeating

No SPOF (single point of failure)

Downside?

All-to-All Heartbeating

Advantage: Everyone is able to keep track of everyone
Downside?

Efficiency of Failure Detector: Metrics

- **Bandwidth**: the number of messages sent in the system during steady state (no failures)
 - Small is good
- **Detection Time**
 - Time between a process crash and its detection
 - Small is good
- **Scalability**: How do bandwidth and detection properties scale with N , the number of processes?
- **Accuracy**
 - Large is good (lower inaccuracy is good)

- **False Detection Rate/False Positive Rate (inaccuracy)**
 - Multiple possible metrics
 - 1. Average number of failures detected per second, when there are in fact no failures
 - 2. Fraction of failure detections that are false
- **Tradeoffs: If you increase the T waiting period in ping-ack or $3 \cdot T$ waiting period in heartbeating what happens to:**
 - Detection Time?
 - False positive rate?
 - Where would you set these waiting periods?

Suspicion

- **Augment failure detection with suspicion count**
- **Ex: In all-to-all heartbeating, suspicion count = number of machines that have timed out waiting for heartbeats from a particular machine M**
 - When suspicion count crosses a threshold, declare M failed
 - Issues: Who maintains this count? If distributed, need to circulate the count
- **Lowers mistaken detections (e.g., message dropped, Internet path bad), e.g., in Cassandra key-value store**
- **Can also keep much longer-term failure counts, and use this to blacklist and greylist machines, e.g., in OpenCorral CDN**

Membership Protocols

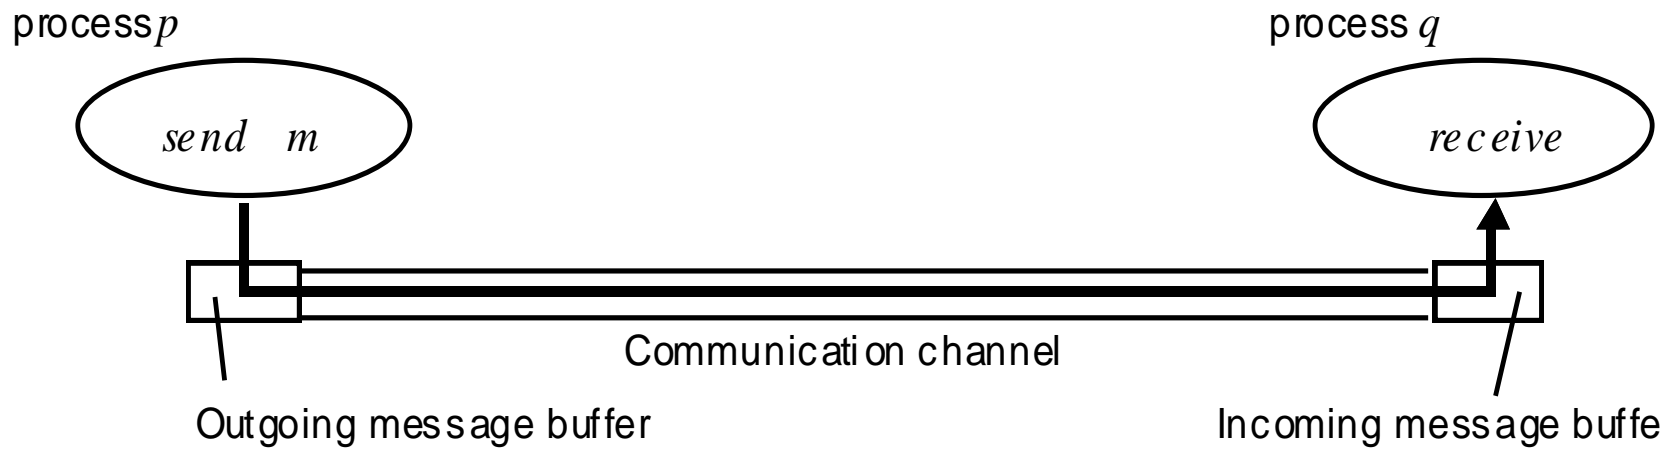

- **Maintain a list of other alive (non-faulty) processes at *each process* in the system**
- **Failure detector is a component in membership protocol**
 - Failure of p_j detected \rightarrow delete p_j from membership list
 - New machine joins $\rightarrow p_j$ sends message to everyone \rightarrow add p_j to membership list
- **Flavors**
 - **Strongly consistent:** all membership lists identical at all times (hard, may not scale)
 - **Weakly consistent:** membership lists not identical at all times
 - **Eventually consistent:** membership lists always moving towards becoming identical eventually (scales well)

Other Types of Failures

- **Let's discuss the other types of failures**
- **Failure detectors exist for them too (but we won't discuss those)**

Processes and Channels

Other Failure Types

□ Communication omission failures

- ❖ **Send-omission: loss of messages between the sending process and the outgoing message buffer (both inclusive)**
 - ❖ **What might cause this?**
- ❖ **Channel omission: loss of message in the communication channel**
 - ❖ **What might cause this?**
- ❖ **Receive-omission: loss of messages between the incoming message buffer and the receiving process (both inclusive)**
 - ❖ **What might cause this?**

Other Failure Types

□ Arbitrary failures

- Arbitrary process failure: arbitrarily omits intended processing steps or takes unintended processing steps.
- Arbitrary channel failures: messages may be corrupted, duplicated, delivered out of order, incur extremely large delays; or non-existent messages may be delivered.
- Above two are **Byzantine** failures, e.g., due to hackers, man-in-the-middle attacks, viruses, worms, etc.
- A variety of Byzantine fault-tolerant protocols have been designed in literature!

Omission and Arbitrary Failures

<i>Class of failure</i>	<i>Affects</i>	<i>Description</i>
Fail-stop or Crash-stop	Process	Process halts and remains halted. Other processes may detect this state.
Omission	Channel	A message inserted in an outgoing message buffer never arrives at the other end's incoming message buffer.
Send-omission	Process	A process completes send , but the message is not put in its outgoing message buffer.
Receive-omission	Process	A message is put in a process's incoming message buffer, but that process does not receive it.
Arbitrary (Byzantine)	Process or channel	Process/channel exhibits arbitrary behaviour: it may send/transmit arbitrary messages at arbitrary times, commit omissions; a process may stop or take an incorrect step.

Summary

- **Failure Detectors**
- **Completeness and Accuracy**
- **Ping-ack and Heartbeating**
- **Suspicion, Membership**

Next Week

- **Next Tuesday: Jack Dorsey**, co-founder of Twitter and founder of Square (mobile payments) is visiting our class 2-2.30pm!
- Townhall-style Q&A
- We are using Google Moderator to post questions, and up/down-vote questions
- Please follow the Google Moderator link from the website – vote and post your own questions!

Next Week

- **Reading for Next Two Lectures: Sections 14.1-14.5**
 - Time and Synchronization
 - Global States and Snapshots
- **HW1 already out, due Sep 20th**
- **MP1 already out, due 9/16: By now you should**
 - Be in a group (send email to us **TODAY**, subject line: “425 MP group”), use Piazza to find partners
 - Have a basic design.
 - If you’ve already started coding, you’re doing well.
