

IP addressing: CIDR

CIDR: Classless InterDomain Routing

- subnet portion of address of arbitrary length
- address format: $a.b.c.d/x$, where x is # bits in subnet portion of address

IP addresses: how to get one?

Q: How does *host* get IP address?

- hard-coded by system admin in a file
 - Wintel: control-panel->network->configuration->tcp/ip->properties
 - UNIX: /etc/rc.config
- **DHCP: Dynamic Host Configuration Protocol:**
dynamically get address from server
 - "plug-and-play"(more in next chapter)

IP addresses: how to get one?

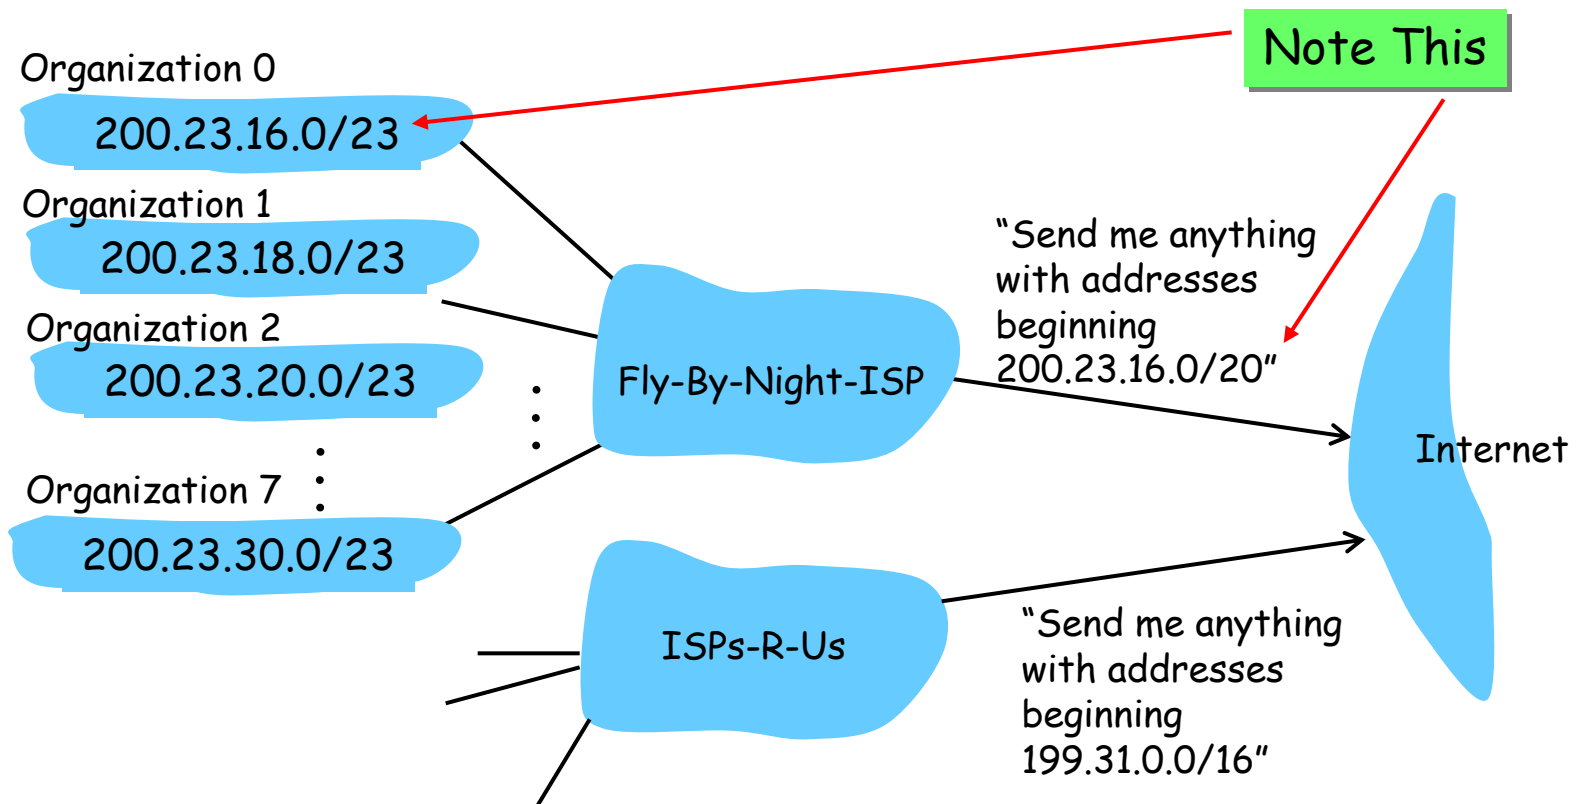

Q: How does *network* get subnet part of IP addr?

A: gets allocated portion of its provider ISP's address space

ISP's block	<u>11001000</u>	<u>00010111</u>	<u>00010000</u>	00000000	200.23.16.0/20
Organization 0	<u>11001000</u>	<u>00010111</u>	<u>00010000</u>	00000000	200.23.16.0/23
Organization 1	<u>11001000</u>	<u>00010111</u>	<u>00010010</u>	00000000	200.23.18.0/23
Organization 2	<u>11001000</u>	<u>00010111</u>	<u>00010100</u>	00000000	200.23.20.0/23
...
Organization 7	<u>11001000</u>	<u>00010111</u>	<u>00011110</u>	00000000	200.23.30.0/23

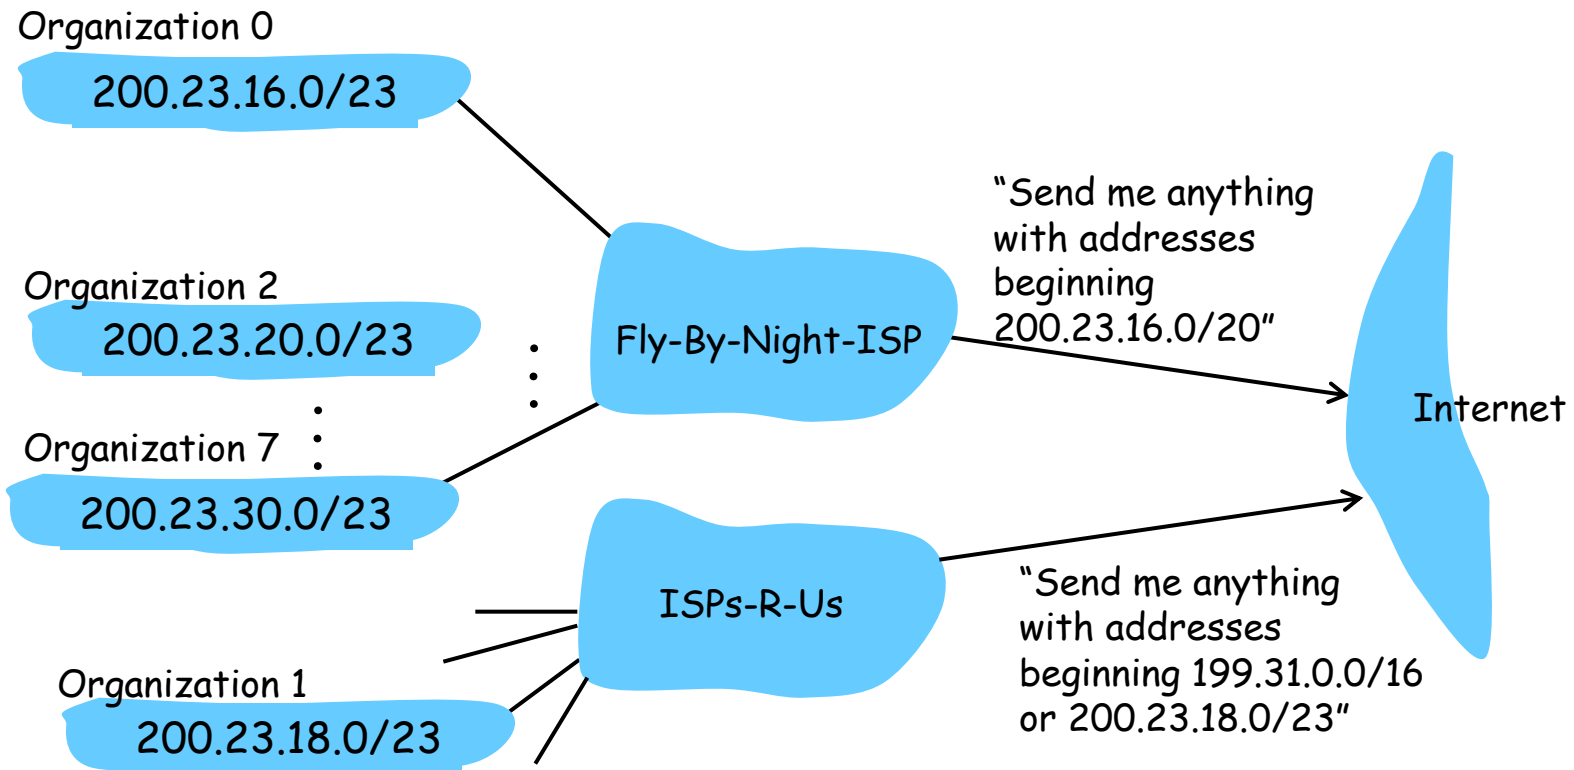

Hierarchical addressing: route aggregation

Hierarchical addressing allows efficient advertisement of routing information:

Hierarchical addressing: more specific routes

ISPs-R-Us has a more specific route to Organization 1

IP addressing: the last word...

Q: How does an ISP get block of addresses?

A: **ICANN:** Internet **C**orporation for **A**ssigned
Names and **N**umbers

- allocates addresses
- manages DNS
- assigns domain names, resolves disputes

NAT: Network Address Translation

All datagrams *leaving* local network have same single source NAT IP address: 138.76.29.7, different source port numbers

Datagrams with source or destination in this network have 10.0.0/24 address for source, destination (as usual)

NAT: Network Address Translation

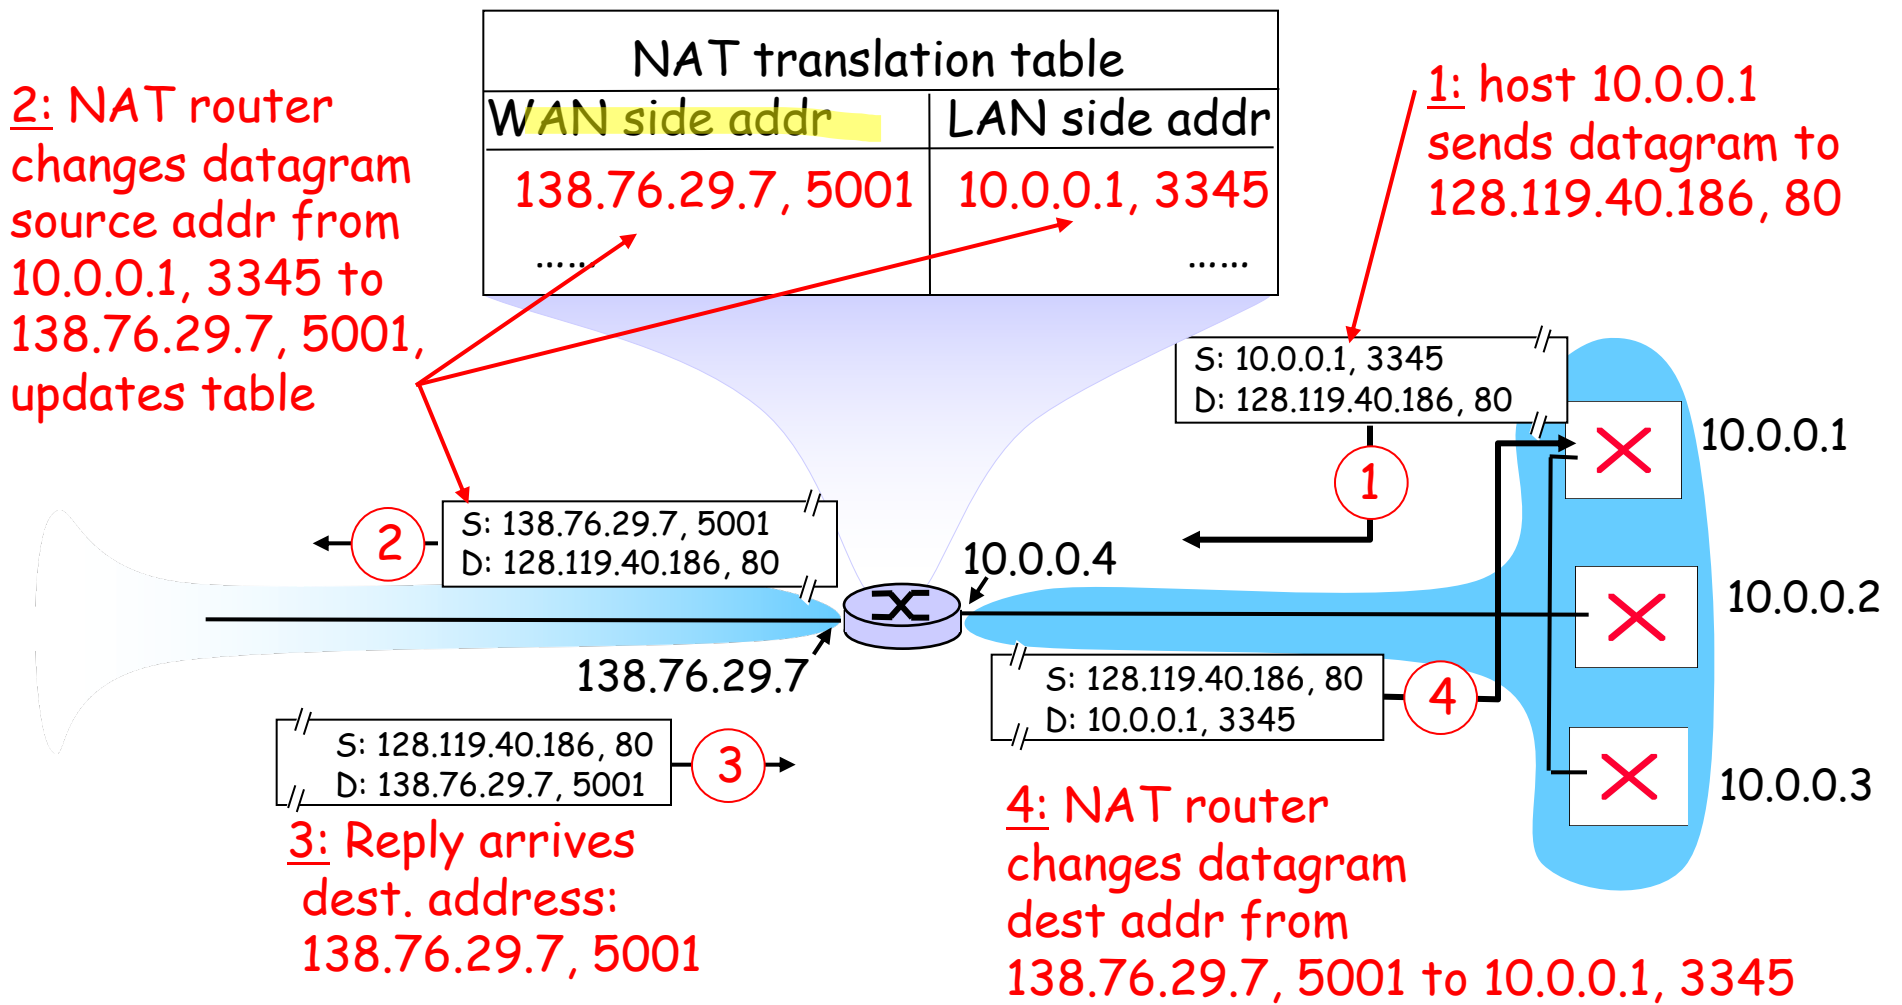

- **Motivation:** local network uses just one IP address as far as outside world is concerned:
 - range of addresses not needed from ISP: just one IP address for all devices
 - can change addresses of devices in local network without notifying outside world
 - can change ISP without changing addresses of devices in local network
 - ○ devices inside local net **NOT** explicitly addressable, visible by outside world (a security plus)

NAT: Network Address Translation

Implementation: NAT router must:

- *outgoing datagrams: replace* (source IP address, port #) of every outgoing datagram to (NAT IP address, new port #)
... remote clients/servers will respond using (NAT IP address, new port #) as destination addr.
- *remember (in NAT translation table) every* (source IP address, port #) to (NAT IP address, new port #) translation pair
- *incoming datagrams: replace* (NAT IP address, new port #) in dest fields of every incoming datagram with corresponding (source IP address, port #) stored in NAT table

NAT: Network Address Translation

NAT: Network Address Translation

- 16-bit port-number field:
 - 60,000 simultaneous connections with a single LAN-side address!
- NAT is controversial:
 - routers should only process up to layer 3
 - violates end-to-end argument
 - NAT possibility must be taken into account by app designers, eg, P2P applications
 - address shortage should instead be solved by IPv6

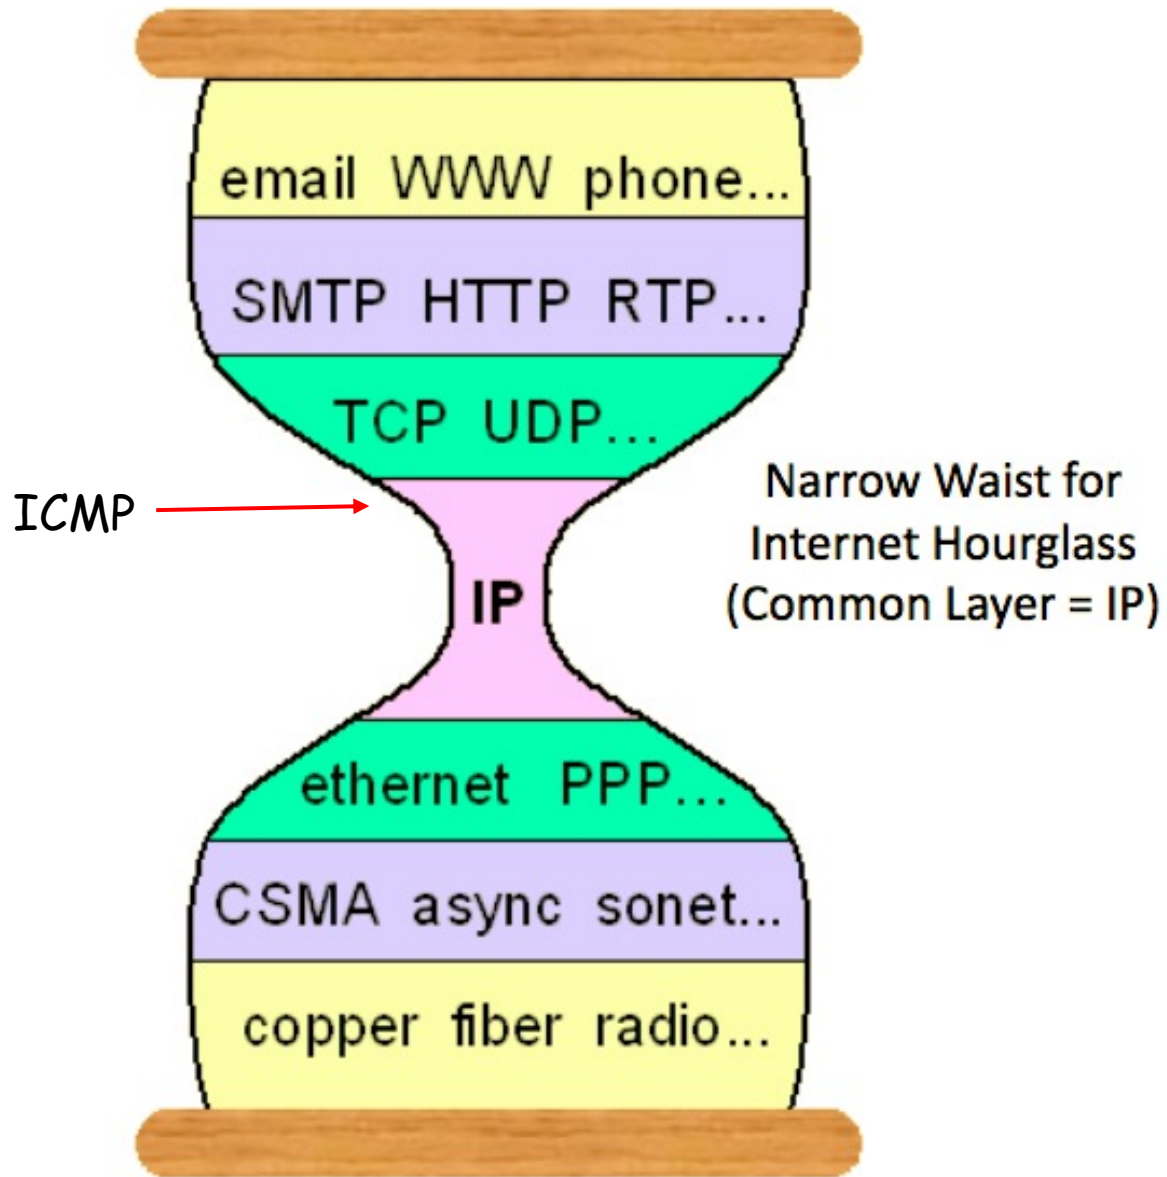

Chapter 4: Network Layer

- ❑ 4.1 Introduction
- ❑ 4.2 Virtual circuit and datagram networks
- ❑ 4.3 What's inside a router
- ❑ 4.4 IP: Internet Protocol
 - Datagram format
 - IPv4 addressing
 - ICMP
 - IPv6
- ❑ 4.5 Routing algorithms
 - Link state
 - Distance Vector
 - Hierarchical routing
- ❑ 4.6 Routing in the Internet
 - RIP
 - OSPF
 - BGP
- ❑ 4.7 Broadcast and multicast routing

ICMP: Internet Control Message Protocol

- used by hosts & routers to communicate network-level information
 - error reporting: unreachable host, network, port, protocol
 - echo request/reply (used by ping)
- network-layer "above" IP:
 - ICMP msgs carried in IP datagrams
- **ICMP message:** type, code plus first 8 bytes of IP datagram causing error

<u>Type</u>	<u>Code</u>	<u>description</u>
0	0	echo reply (ping)
3	0	dest. network unreachable
3	1	dest host unreachable
3	2	dest protocol unreachable
3	3	dest port unreachable
3	6	dest network unknown
3	7	dest host unknown
4	0	source quench (congestion control - not used)
8	0	echo request (ping)
9	0	route advertisement
10	0	router discovery
11	0	TTL expired
12	0	bad IP header

Traceroute and ICMP

- ❑ Source sends series of UDP segments to dest
 - First has TTL =1
 - Second has TTL=2, etc.
 - ❑ When nth datagram arrives to nth router:
 - Router discards datagram
 - And sends to source an ICMP message (type 11, code 0)
 - Message includes name of router & IP address
 - ❑ When ICMP message arrives, source calculates RTT
 - ❑ Traceroute does this 3 times
- Stopping criterion
- ❑ UDP segment eventually arrives at destination host
 - ❑ Destination returns ICMP "host unreachable" packet (type 3, code 3)
 - ❑ When source gets this ICMP, stops.

Chapter 4: Network Layer

- ❑ 4.1 Introduction
- ❑ 4.2 Virtual circuit and datagram networks
- ❑ 4.3 What's inside a router
- ❑ 4.4 IP: Internet Protocol
 - Datagram format
 - IPv4 addressing
 - ICMP
 - IPv6
- ❑ 4.5 Routing algorithms
 - Link state
 - Distance Vector
 - Hierarchical routing
- ❑ 4.6 Routing in the Internet
 - RIP
 - OSPF
 - BGP
- ❑ 4.7 Broadcast and multicast routing

IPv6

- **Initial motivation:** 32-bit address space soon to be completely allocated.
 - **Additional motivation:**
 - header format helps speed processing/forwarding
 - header changes to facilitate QoS
- IPv6 datagram format:**
- fixed-length 40 byte header
 - no fragmentation allowed

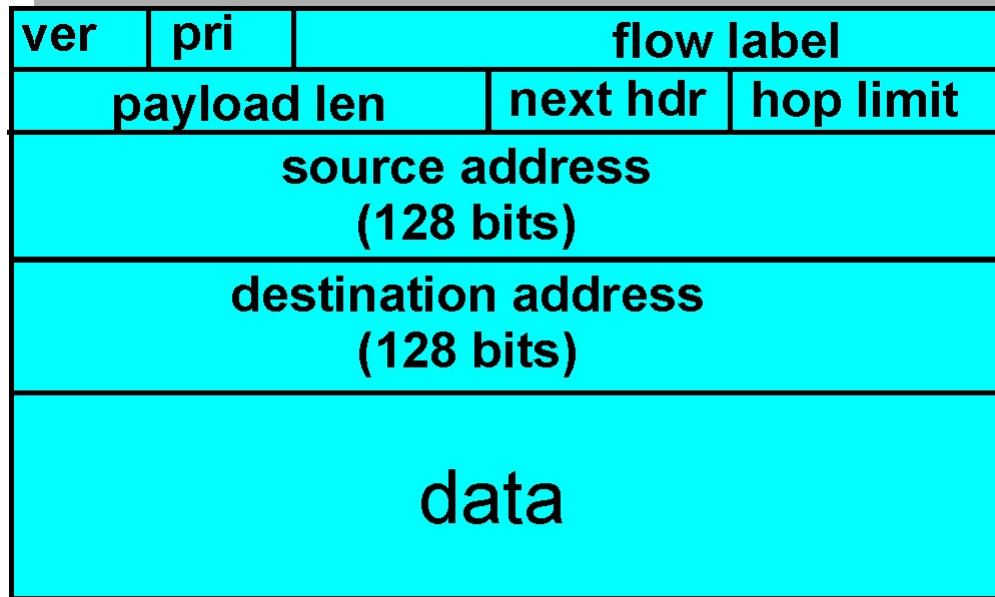

IPv6 Header (Cont)

Priority: identify priority among datagrams in flow

Flow Label: identify datagrams in same "flow."

(concept of "flow" not well defined).

Next header: identify upper layer protocol for data

← 32 bits →

Other Changes from IPv4

- ❑ *Checksum*: removed entirely to reduce processing time at each hop
- ❑ *Options*: allowed, but outside of header, indicated by "Next Header" field
- ❑ *ICMPv6*: new version of ICMP
 - additional message types, e.g. "Packet Too Big"
 - multicast group management functions

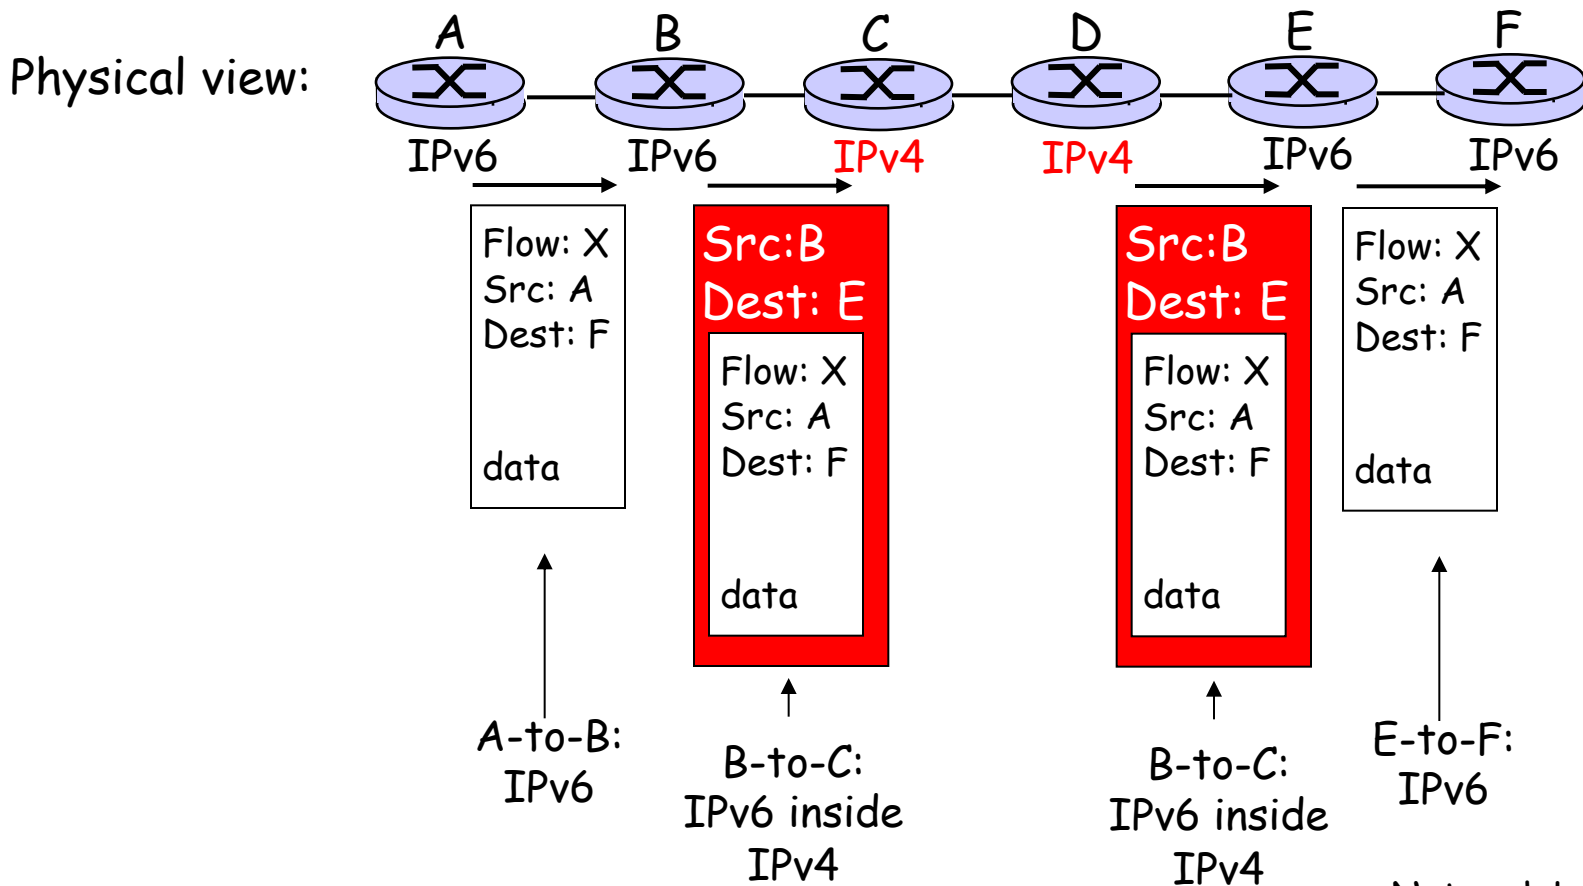

Transition From IPv4 To IPv6

- ❑ Not all routers can be upgraded simultaneous
 - no “flag days”
 - How will the network operate with mixed IPv4 and IPv6 routers?
- ❑ *Tunneling*: IPv6 carried as payload in IPv4 datagram among IPv4 routers

Tunneling

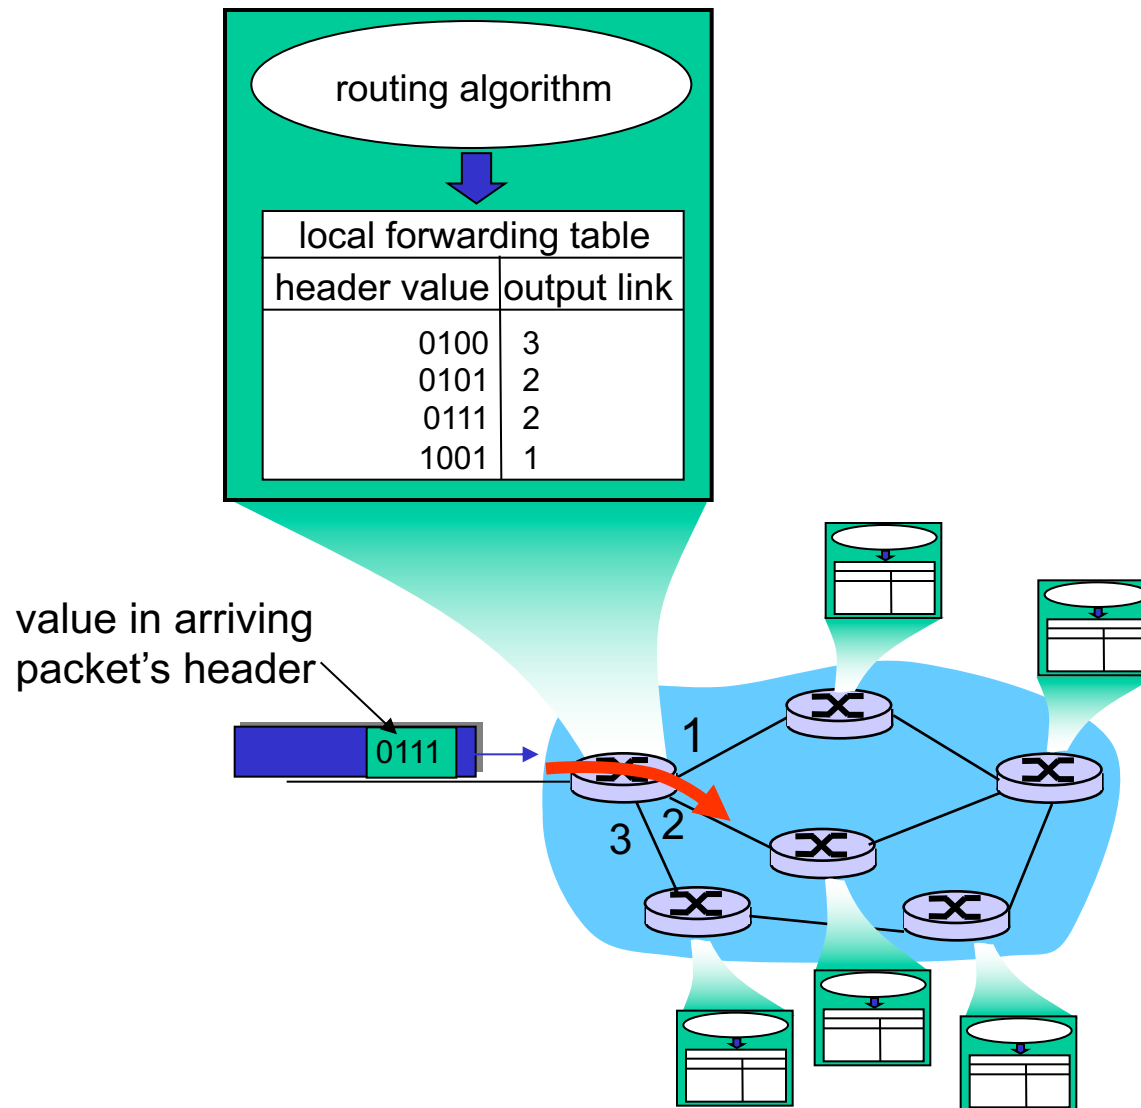

Tunneling

Chapter 4: Network Layer

- ❑ 4.1 Introduction
- ❑ 4.2 Virtual circuit and datagram networks
- ❑ 4.3 What's inside a router
- ❑ 4.4 IP: Internet Protocol
 - Datagram format
 - IPv4 addressing
 - ICMP
 - IPv6
- ❑ 4.5 **Routing algorithms**
 - Link state
 - Distance Vector
 - Hierarchical routing
- ❑ 4.6 Routing in the Internet
 - RIP
 - OSPF
 - BGP
- ❑ 4.7 Broadcast and multicast routing

Interplay between routing, forwarding

Graph abstraction

Graph: $G = (N,E)$

$N = \text{set of routers} = \{ u, v, w, x, y, z \}$

$E = \text{set of links} = \{ (u,v), (u,x), (v,x), (v,w), (x,w), (x,y), (w,y), (w,z), (y,z) \}$

Remark: Graph abstraction is useful in other network contexts

Example: P2P, where N is set of peers and E is set of TCP connections

Graph abstraction: costs

- $c(x,x')$ = cost of link (x,x')

- e.g., $c(w,z) = 5$

- cost could always be 1, or inversely related to bandwidth, or inversely related to congestion

Cost of path $(x_1, x_2, x_3, \dots, x_p) = c(x_1, x_2) + c(x_2, x_3) + \dots + c(x_{p-1}, x_p)$

Question: What's the least-cost path between u and z ?

Routing algorithm: algorithm that finds least-cost path

Routing Algorithm classification

Global or decentralized information?

Global:

- ❑ all routers have complete topology, link cost info
- ❑ "link state" algorithms

Decentralized:

- ❑ router knows physically-connected neighbors, link costs to neighbors
- ❑ iterative process of computation, exchange of info with neighbors
- ❑ "distance vector" algorithms

Static or dynamic?

Static:

- ❑ routes change slowly over time

Dynamic:

- ❑ routes change more quickly
 - periodic update
 - in response to link cost changes

Chapter 4: Network Layer

- ❑ 4.1 Introduction
- ❑ 4.2 Virtual circuit and datagram networks
- ❑ 4.3 What's inside a router
- ❑ 4.4 IP: Internet Protocol
 - Datagram format
 - IPv4 addressing
 - ICMP
 - IPv6
- ❑ 4.5 Routing algorithms
 - Link state
 - Distance Vector
 - Hierarchical routing
- ❑ 4.6 Routing in the Internet
 - RIP
 - OSPF
 - BGP
- ❑ 4.7 Broadcast and multicast routing

A Link-State Routing Algorithm

Dijkstra's algorithm

- ❑ net topology, link costs known to all nodes
 - accomplished via "link state broadcast"
 - all nodes have same info
- ❑ computes least cost paths from one node ('source") to all other nodes
 - gives forwarding table for that node
- ❑ iterative: after k iterations, know least cost path to k dest.'s

Notation:

- ❑ $c(x,y)$: link cost from node x to y ; $= \infty$ if not direct neighbors
- ❑ $D(v)$: current value of cost of path from source to dest. v
- ❑ $p(v)$: predecessor node along path from source to v
- ❑ N' : set of nodes whose least cost path definitively known

Dijsktra's Algorithm

```
1 Initialization:  
2  N' = {u}  
3  for all nodes v  
4    if v adjacent to u  
5      then D(v) = c(u,v)  
6    else D(v) = ∞  
7  
8 Loop  
9  find w not in N' such that D(w) is a minimum  
10 add w to N'  
11 update D(v) for all v adjacent to w and not in N' :  
12   D(v) = min( D(v), D(w) + c(w,v) )  
13 /* new cost to v is either old cost to v or known  
14    shortest path cost to w plus cost from w to v */  
15 until all nodes in N'
```
