

CS/ECE 439: Wireless Networking

Infrastructureless Wireless Networks

When the network just isn't there ...

- ▶ **Ad hoc networks**
 - ▶ Group of cooperating nodes
 - ▶ Nodes are mobile
 - ▶ Paths eventually exist between a src/dst pair
 - ▶ All nodes are routers
- ▶ **Sensor networks**
 - ▶ Similar to ad hoc networks
 - ▶ Nodes are typically non-mobile
 - ▶ Target long operating lifetimes
- ▶ **Opportunistic networks**
 - ▶ Nodes are mobile
 - ▶ Paths may never exist between a src/dst pair
 - ▶ Store-carry-forward

Ad Hoc Networks

- ▶ Formed by wireless hosts that may be mobile
- ▶ Without (necessarily) using a pre-existing infrastructure
- ▶ Routes between nodes may potentially contain multiple hops
 - ▶ Mobility causes route changes

Why Ad Hoc Networks ?

- ▶ Ease of deployment
- ▶ Speed of deployment
- ▶ Decreased dependence on infrastructure

Many Variations

- ▶ **Fully Symmetric Environment**
 - ▶ All nodes have identical capabilities and responsibilities
- ▶ **Asymmetric Capabilities**
 - ▶ Transmission ranges and radios may differ
 - ▶ Battery life at different nodes may differ
 - ▶ Processing capacity may be different at different nodes
 - ▶ Speed of movement
- ▶ **Asymmetric Responsibilities**
 - ▶ Only some nodes may route packets
 - ▶ Some nodes may act as leaders of nearby nodes (e.g., cluster head)

Many Variations

- ▶ Traffic characteristics may differ in different ad hoc networks
 - ▶ Bit rate
 - ▶ Timeliness constraints
 - ▶ Reliability requirements
 - ▶ Unicast / multicast / geocast
 - ▶ Host-based addressing / content-based addressing / capability-based addressing

- ▶ May co-exist (and co-operate) with an infrastructure-based network

Many Variations

- ▶ **Mobility characteristics**
 - ▶ Speed
 - ▶ Predictability
 - ▶ Direction of movement
 - ▶ Pattern of movement
 - ▶ Uniformity (or lack thereof) of mobility characteristics among different nodes

Challenges

- ▶ Limited wireless transmission range
- ▶ Broadcast nature of the wireless medium
 - ▶ Hidden terminal problem
- ▶ Packet losses due to transmission errors
- ▶ Mobility-induced route changes
- ▶ Mobility-induced packet losses
- ▶ Battery constraints
- ▶ Potentially frequent network partitions
- ▶ Ease of snooping on wireless transmissions

The Holy Grail

- ▶ **A one-size-fits-all solution**
 - ▶ Perhaps using an adaptive/hybrid approach that can adapt to situation at hand
- ▶ **Difficult problem**
- ▶ **Many solutions proposed trying to address a sub-space of the problem domain**

Unicast Routing in Ad Hoc Networks

Why is routing in wireless ad hoc networks different/difficult?

- ▶ **Link instability causes many routing issues**
 - ▶ Shortest hop routing often worst choice
 - ▶ Scarce bandwidth makes overhead conspicuous
 - ▶ Battery power a concern
 - ▶ Security and misbehavior ...
- ▶ **Host mobility**
 - ▶ Link failure/repair due to mobility may have different characteristics than those due to other causes
 - ▶ Rate of link failure/repair may be high when nodes move fast
- ▶ **New performance criteria may be used**
 - ▶ Route stability despite mobility
 - ▶ Energy consumption

Routing in Mobile Networks

- ▶ Imagine hundreds of hosts moving
 - ▶ Routing algorithm needs to cope up with varying wireless channel and node mobility

Unicast Routing Protocols

- ▶ **Many protocols have been proposed**
 - ▶ Some have been invented specifically for ad hoc networks
 - ▶ Others are adapted from wired network routing

- ▶ **No single protocol works well in all environments**
 - ▶ Some attempts made to develop adaptive protocols

Routing Protocols

- ▶ **Proactive protocols**

- ▶ Determine routes independent of traffic pattern
- ▶ Traditional link-state and distance-vector routing protocols are proactive

- ▶ **Reactive protocols**

- ▶ Maintain routes only if needed

- ▶ **Hybrid protocols**

- ▶ Maintain routes to nearby nodes
- ▶ Discover routes for far away nodes

Trade-Off

- ▶ **Latency of route discovery**
 - ▶ Proactive protocols
 - ▶ May have lower latency since routes are maintained at all times
 - ▶ Reactive protocols
 - ▶ May have higher latency because a route from X to Y will be found only when X attempts to send to Y

Trade-Off

- ▶ **Overhead of route discovery/maintenance**
 - ▶ Reactive protocols
 - ▶ May have lower overhead since routes are determined only if needed
 - ▶ Proactive protocols
 - ▶ Can (but not necessarily) result in higher overhead due to continuous route updating
- ▶ Which approach achieves a better trade-off depends on the traffic and mobility patterns

Flooding for Data Delivery

- ▶ **Sender**
 - ▶ Broadcasts data packet P to all its neighbors
- ▶ **Intermediate nodes**
 - ▶ Forward P to its neighbors
- ▶ **Sequence numbers**
 - ▶ Used to avoid the possibility of forwarding the same packet more than once
- ▶ **Destination**
 - ▶ Packet P reaches destination D provided that D is reachable from sender S
 - ▶ Node D does not forward the packet

Flooding for Data Delivery

nodes that have received packet

Flooding for Data Delivery

Flooding for Data Delivery

- ▶ Node H receives packet from two neighbors:
potential for collision

Flooding for Data Delivery

- ▶ Node C receives packet from G and H, but does not forward it again, because node C has already forwarded that packet once

Flooding for Data Delivery

- ▶ Nodes J and K both broadcast packet to node D
 - ▶ Since nodes J and K are **hidden** from each other, their **transmissions may collide**

Flooding for Data Delivery

- ▶ Nodes J and K both broadcast packet to node D
=> Packet may not be delivered to node D at all, despite the use of flooding

Flooding for Data Delivery

- ▶ Node D **does not forward** packet, because node D is the **intended destination**

Flooding for Data Delivery

▶ Flooding completed

- ▶ Nodes **unreachable** from S do not receive packet (e.g., Z)
- ▶ Nodes for which all paths from S go through D also do not receive packet (example: N)

Flooding for Data Delivery

- ▶ Flooding may deliver packets to too many nodes
- ▶ **worst case**, all nodes reachable from sender may receive the packet

Flooding for Data Delivery: Advantages

- ▶ **Simplicity**
- ▶ **Efficiency**
 - ▶ Low rate of information transmission
 - ▶ Overhead of explicit route discovery/maintenance incurred by other protocols is relatively higher
 - ▶ For example, when nodes transmit small data packets relatively infrequently, and many topology changes occur between consecutive packet transmissions
- ▶ **Potentially higher reliability of data delivery**
 - ▶ Because packets may be delivered to the destination on multiple paths

Flooding for Data Delivery: Disadvantages

- ▶ **Potentially, very high overhead**
 - ▶ Data packets may be delivered to too many nodes who do not need to receive them
- ▶ **Potentially lower reliability of data delivery**
 - ▶ Flooding uses broadcasting
 - ▶ Hard to implement reliable broadcast
 - Broadcast in IEEE 802.11 MAC is unreliable
 - ▶ e.g., nodes J and K may transmit to node D simultaneously, resulting in loss of the packet
 - ▶ In this case, destination would not receive the packet at all

Flooding of Control Packets

- ▶ Many protocols perform (potentially limited) flooding of control packets, instead of data packets
 - ▶ The control packets are used to discover routes
 - ▶ Discovered routes are subsequently used to send data packet(s)
- ▶ Overhead of control packet flooding is amortized over data packets transmitted between consecutive control packet floods

Dynamic Source Routing (DSR)

▶ Route Discovery

- ▶ When node S wants to send a packet to node D , but does not know a route to D , node S initiates a route discovery
- ▶ Source node S floods Route Request (RREQ)
- ▶ Each node appends own identifier when forwarding RREQ

Route Discovery in DSR

Route Discovery in DSR

- ▶ $[X, Y]$: list of identifiers appended to RREQ

Route Discovery in DSR

- ▶ Node H receives packet RREQ from two neighbors: **potential for collision**

Route Discovery in DSR

- ▶ Node C receives RREQ from G and H
 - ▶ Node C does not forward it again, because node C has **already forwarded RREQ** once

Route Discovery in DSR

- ▶ Nodes J and K both broadcast RREQ to node D
- ▶ Since nodes J and K are **hidden** from each other, their **transmissions may collide**

Route Discovery in DSR

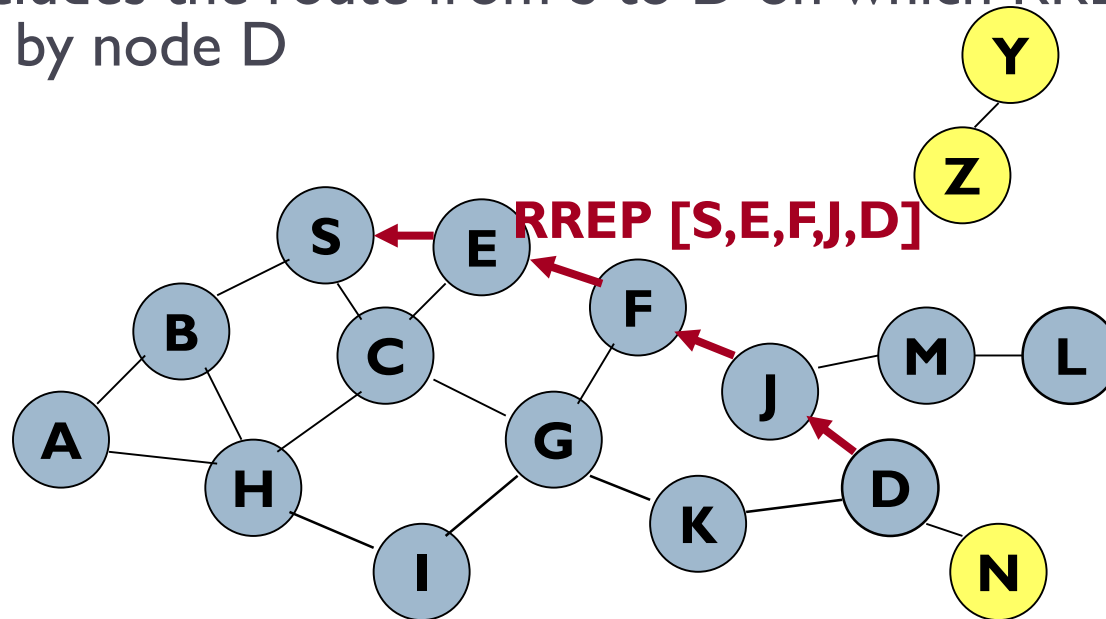

- ▶ Node D **does not forward** RREQ, because node D is the **intended target** of the route discovery

Route Reply in DSR

► Destination D

- On receiving the first RREQ, send a Route Reply (RREP)
- RREP is sent on a route obtained by reversing the route appended to received RREQ
- RREP includes the route from S to D on which RREQ was received by node D

Route Reply in DSR

- ▶ **Route Reply**
 - ▶ Bi-directional links
 - ▶ Reverse route in Route Request (RREQ)
 - ▶ RREQ should be forwarded only if received on a link that is known to be bi-directional
 - ▶ Unidirectional (asymmetric) links
 - ▶ RREP may need a route discovery for S from node D
 - Route Reply is piggybacked on the Route Request from D
 - ▶ Unless node D already knows a route to node S

- ▶ **IEEE 802.11 MAC**
 - ▶ Links must be bi-directional (since ACK is used)

Dynamic Source Routing (DSR)

- ▶ **On receiving RREP**
 - ▶ Cache the route included in the RREP
- ▶ **Sending**
 - ▶ The entire route is included in the packet header
 - ▶ Hence the name source routing
- ▶ **Intermediate nodes**
 - ▶ Use the source route included in a packet to determine to whom a packet should be forwarded

Data Delivery in DSR

- ▶ Packet header size grows with route length

When to Perform a Route Discovery

- ▶ When node S wants to send data to node D, but does not know a valid route node D

DSR Optimization: Route Caching

▶ Caching

- ▶ Each node caches a new route it learns by any means
- ▶ Snooping
 - ▶ A node may also learn a route when it overhears Data packets

▶ Use of Route Caching

- ▶ Broken routes
 - ▶ Use another route from the local cache
 - ▶ Otherwise, initiate new route discovery
- ▶ Intermediate response
 - ▶ On receiving a Route Request for some node D
 - Node X can send a Route Reply if node X knows a route to node D
- ▶ Use of route cache
 - ▶ Speed up route discovery
 - ▶ Reduce propagation of route requests

Use of Route Caching

- ▶ **Broken routes**
 - ▶ Use another route from the local cache
 - ▶ Otherwise, initiate new route discovery
- ▶ **Intermediate response**
 - ▶ On receiving a Route Request for some node D
 - ▶ Node X can send a Route Reply if node X knows a route to node D
- ▶ **Use of route cache**
 - ▶ Speed up route discovery
 - ▶ Reduce propagation of route requests

Use of Route Caching

- ▶ **[P,Q,R]** Represents cached route at a node
 - ▶ DSR maintains the cached routes in a tree format

Use of Route Caching: Speed up Route Discovery

- ▶ **Z** sends a route request for node **C**
 - ▶ Node **K** sends back a route reply $[Z, K, G, C]$ to node **Z** using a locally cached route

Use of Route Caching: Reduce of Route Requests

- ▶ No link between D and Z
 - ▶ Route Reply (RREP) from node K **limits flooding** of RREQ
 - ▶ In general, the reduction may be less dramatic.

Route Error (RERR)

- ▶ When attempt to forward the data packet S (with route SEFJD) on J-D fails
 - ▶ J sends a route error to S along J-F-E-S
 - ▶ Nodes hearing RERR update their route cache to remove link J-D

Route Caching: Beware!

- ▶ **Stale caches**
 - ▶ Can adversely affect performance
- ▶ **Timeliness**
 - ▶ With passage of time and host mobility, cached routes may become invalid
- ▶ **Know when to give up**
 - ▶ A sender host may try several stale routes (obtained from local cache, or replied from cache by other nodes), before finding a good route

Dynamic Source Routing: Advantages

▶ On-demand

- ▶ Routes maintained only between nodes that need to communicate
- ▶ Reduces overhead of route maintenance

▶ Route caching

- ▶ Can further reduce route discovery overhead
- ▶ A single route discovery may yield many routes to the destination, due to intermediate nodes replying from local caches

Dynamic Source Routing: Disadvantages

▶ Size

- ▶ Packet header size grows with route length

▶ Packets

- ▶ Flood of route requests may reach all nodes

▶ Timing

- ▶ Must avoid route requests collisions
 - ▶ Insertion of random delays before forwarding RREQ
- ▶ Route Reply Storm problem
 - ▶ Too many nodes reply using local cache
 - ▶ Prevent a node from sending RREP if it hears another RREP with a shorter route

Dynamic Source Routing: Disadvantages

▶ Pollution

- ▶ An intermediate node may send Route Reply using a stale cached route
- ▶ Need some mechanism to purge (potentially) invalid cached routes

▶ For some proposals for cache invalidation

- ▶ Static timeouts
- ▶ Adaptive timeouts based on link stability

Flooding of Control Packets

- ▶ How to reduce the scope of the route request flood ?
 - ▶ LAR
- ▶ How to reduce redundant broadcasts ?
 - ▶ The Broadcast Storm Problem

Location-Aided Routing (LAR)

- ▶ **Exploit location information to limit scope of flood**
 - ▶ Location information may be obtained using GPS
- ▶ **Expected Zone**
 - ▶ A region that is expected to hold the current location of the destination
 - ▶ Determined based on potentially old location information and knowledge of the destination's speed
- ▶ **Route requests limited to a Request Zone that contains the Expected Zone and location of the sender node**

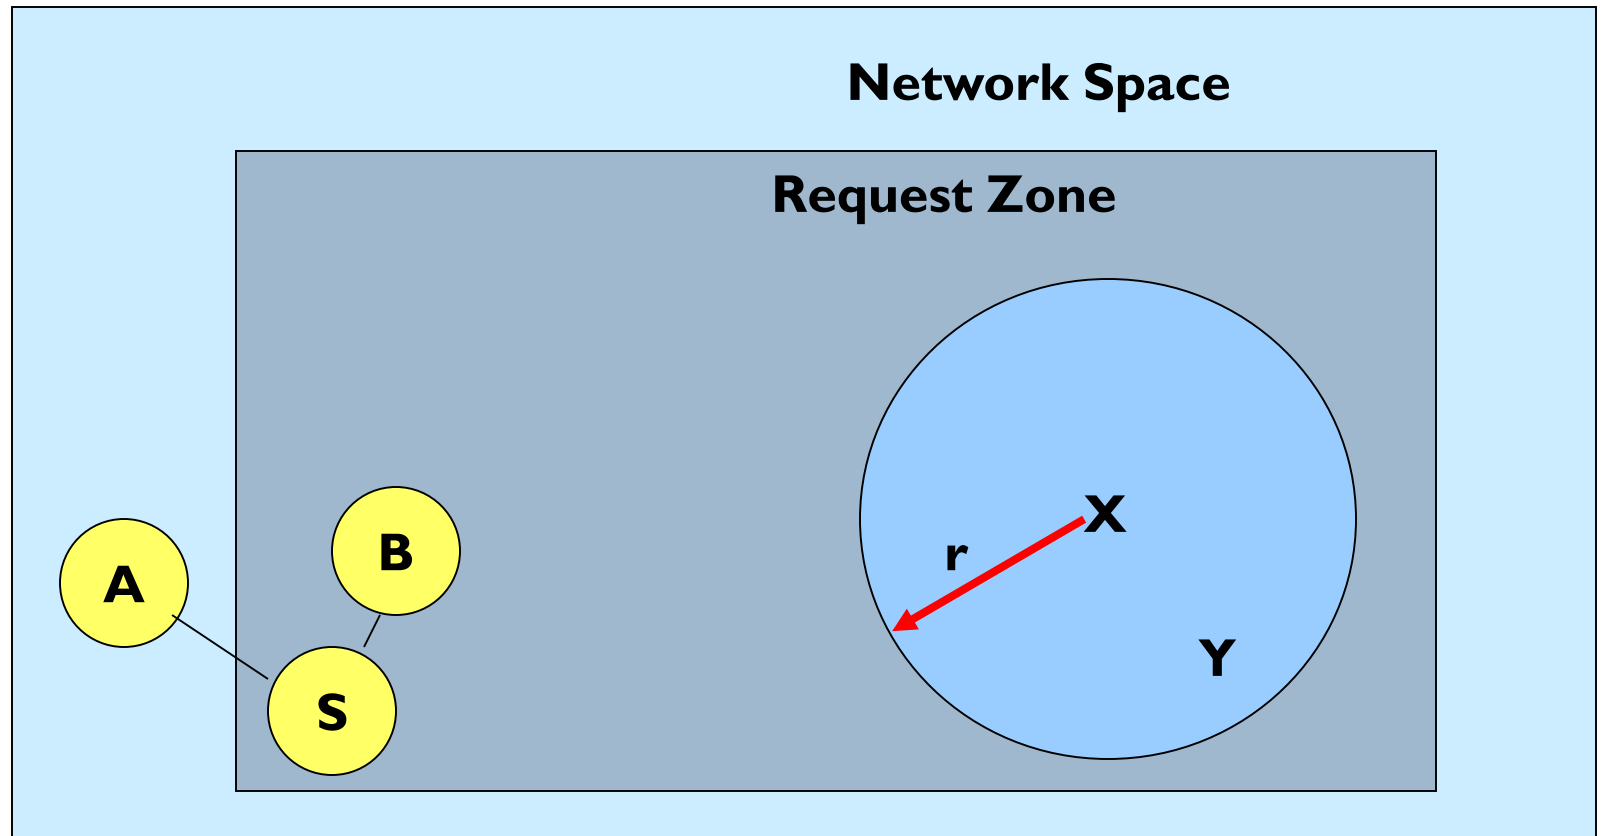

Expected Zone in LAR

- ▶ X = last known location of node D, at time t_0
- ▶ Y = location of node D at current time t_1 , unknown to node S
- ▶ $r = (t_1 - t_0) * \text{estimate of D's speed}$

Expected Zone

Request Zone in LAR

LAR

▶ Zone

- ▶ Explicitly specified in the route request
- ▶ Each node must know its physical location to determine whether it is within the request zone

▶ Forwarding

- ▶ Only nodes within the request zone forward route requests

▶ Failure

- ▶ Initiate another route discovery (after a timeout) using a larger request zone
- ▶ the larger request zone may be the entire network

▶ Rest of route discovery protocol similar to DSR

Location Aided Routing (LAR)

▶ Advantages

- ▶ Reduces the scope of route request flood
- ▶ Reduces overhead of route discovery

▶ Disadvantages

- ▶ Nodes need to know their physical locations
- ▶ Does not take into account possible existence of obstructions for radio transmissions

Broadcast Storm Problem

- ▶ When node A broadcasts a route query, nodes B and C both receive it
 - ▶ B and C both forward to their neighbors
 - ▶ B and C transmit at about the same time since they are reacting to receipt of the same message from A
 - ▶ This results in a high probability of collisions

Broadcast Storm Problem

▶ Redundancy

- ▶ A given node may receive the same route request from too many nodes, when one copy would have sufficed
- ▶ Node D may receive from nodes B and C

Solutions for Broadcast Storm

▶ Probabilistic scheme

- ▶ Re-broadcast (forward) the request with probability p
- ▶ Re-broadcasts by different nodes should be staggered by using a collision avoidance technique
- ▶ Reduce the probability that nodes B and C would forward a packet simultaneously

Solutions for Broadcast Storm

▶ Counter-Based Scheme

- ▶ If node E hears more than k neighbors broadcasting a given route request, before it can itself forward it, then node E will not forward the request

▶ Intuition

- ▶ k neighbors together have probably already forwarded the request to all of E's neighbors

Solutions for Broadcast Storm

- ▶ **Distance-Based Scheme**
 - ▶ If node E hears RREQ broadcasted by some node Z within physical distance d , then E will not re-broadcast the request
- ▶ **Intuition**
 - ▶ Z and E are close, so transmission areas covered by Z and E are not very different

Summary: Broadcast Storm Problem

- ▶ Flooding is used in many protocols, such as Dynamic Source Routing (DSR)
- ▶ Problems associated with flooding
 - ▶ Collisions
 - ▶ May be reduced by “jittering” (waiting for a random interval before propagating the flood)
 - ▶ Redundancy
 - ▶ May be reduced by selectively re-broadcasting packets from only a subset of the nodes

Ad Hoc On-Demand Distance Vector Routing (AODV)

- ▶ **Source routing**

- ▶ Large headers
- ▶ Particularly when data contents of a packet are small

- ▶ **AODV**

- ▶ Maintaining routing tables at the nodes
- ▶ Routes are maintained only between nodes which need to communicate

AODV

- ▶ **Route Requests (RREQ)**
 - ▶ Forwarded in a manner similar to DSR
- ▶ **Routes**
 - ▶ When a node re-broadcasts a Route Request, it sets up a reverse path pointing towards the source
 - ▶ AODV assumes symmetric (bi-directional) links
- ▶ **Destination**
 - ▶ Destination replies to Route Request with a Route Reply
- ▶ **Route Reply**
 - ▶ Follows reverse path set-up by Route Request

Route Requests in AODV

Route Requests in AODV

Broadcast transmission

Route Requests in AODV

Reverse Path Setup in AODV

- ▶ Node C receives RREQ from G and H, but does not forward it again, because node C has **already forwarded RREQ** once

Reverse Path Setup in AODV

Reverse Path Setup in AODV

- ▶ Node D **does not forward** RREQ, because node D is the **intended target** of the RREQ

Route Reply in AODV

Route Reply in AODV

- ▶ **Intermediate node reply**
 - ▶ Send a Route Reply (RREP) if it knows a more recent path than the one previously known to sender
- ▶ **Sequence Numbers**
 - ▶ Destination sequence numbers are used to determine age
- ▶ **Fewer intermediate replies than DSR**
 - ▶ A new Route Request for a destination is assigned a higher destination sequence number
 - ▶ An intermediate node that knows a route with a smaller sequence number cannot send Route Reply

Forward Path Setup in AODV

- ▶ Forward links are setup when RREP travels along the reverse path

Data Delivery in AODV

- ▶ Routing table entries used to forward data packet
- ▶ Route is *not* included in packet header

Timeouts

- ▶ **Routing table entries**

- ▶ **Reverse Paths**

- ▶ Purged after a timeout interval
 - ▶ Timeout should be long enough to allow RREP to come back

- ▶ **Forward Paths**

- ▶ If no is data being sent using a particular routing table entry
 - Entry is deleted from the routing table (even if the route may actually still be valid)

Link Failure Reporting

- ▶ **Link Failure**
 - ▶ When the next hop link in a routing table entry breaks, all active neighbors are informed
 - ▶ Active neighbors
 - ▶ Any neighbor that sent a packet within `active_route_timeout` interval which was forwarded using that entry
- ▶ **Link failures**
 - ▶ Propagated by means of Route Error messages
 - ▶ Also update destination sequence numbers

Link Failure Detection

- ▶ **Hello messages**

- ▶ Neighboring nodes periodically exchange hello message
- ▶ Absence of hello message is used as an indication of link failure

- ▶ **Alternatively**

- ▶ Failure to receive several MAC-level acknowledgement may be used as an indication of link failure

Why Sequence Numbers in AODV

- ▶ To avoid using old/broken routes
 - ▶ To determine which route is newer
- ▶ To prevent formation of loops

- ▶ RERR sent by C is lost
 - ▶ A does not know about failure of link C-D
- ▶ C performs a route discovery for D
 - ▶ Node A receives the RREQ (say, via path C-E-A)
- ▶ Node A replies since A knows a route to D via node B
- ▶ Results in a loop (for instance, C-E-A-B-C)

Why Sequence Numbers in AODV

▶ Loop C-E-A-B-C

Optimization: Expanding Ring Search

▶ Route Requests

- ▶ Initially sent with small Time-to-Live (TTL) field, to limit propagation
- ▶ DSR also includes a similar optimization

▶ If no Route Reply is received

- ▶ Larger TTL

Summary: AODV

- ▶ Routes need not be included in packet headers
- ▶ Nodes maintain routing tables
 - ▶ Entries only for routes that are in active use
- ▶ At most one next-hop per destination maintained at each node
 - ▶ DSR may maintain several routes for a single destination
- ▶ Unused routes expire even if topology does not change

Some Variations

Power-Aware Routing

- ▶ Define optimization criteria as a function of energy consumption
- ▶ Examples
 - ▶ Minimize energy consumed per packet
 - ▶ Minimize time to network partition due to energy depletion
 - ▶ Maximize duration before a node fails due to energy depletion

Power-Aware Routing

- ▶ Assign a weight to each link
- ▶ Weight of a link may be a function of
 - ▶ Energy consumed when transmitting a packet
 - ▶ Residual energy level
 - ▶ Low residual energy level may correspond to a high cost
- ▶ Prefer a route with the smallest aggregate weight

Link Stability-Based Routing

▶ Idea

- ▶ A node X re-broadcasts a Route Request received from Y only if the (X,Y) link is deemed to have a strong signal stability

▶ Signal stability

- ▶ Evaluated as a moving average of the signal strength of packets received on the link in recent past

▶ Alternative approach

- ▶ Assign a cost as a function of signal stability

Connection Stability-Based Routing

- ▶ **Only utilize links that have been stable for some minimum duration**
 - ▶ If a link has been stable beyond some minimum threshold
 - ▶ It is likely to be stable for a longer interval
 - ▶ If it has not been stable longer than the threshold
 - ▶ It may soon break (could be a transient link)
- ▶ **Prefer paths with high aggregate stability**
