

# CS/ECE 439: Wireless Networking

MAC Layer – Power!

# Energy Conservation Techniques

---

- ▶ Wi-Fi devices consume significant amounts of energy when idle
  - ▶ Idle  $> 1W$
- ▶ Conservation Approach: Device suspension (sleep)
  - ▶ Reduced energy consumption
    - ▶ Sleep  $\sim 0.05W$
  - ▶ Suspended communication capabilities
    - ▶ Buffer overflow
    - ▶ Wasted bandwidth
    - ▶ Lost messages
    - ▶ If all nodes are asleep, no one can communicate!

# Communication Device Suspension

---

## ▶ Goal

- ▶ Remain awake when there is active communication
- ▶ Otherwise, suspend
- ▶ Adapt the sleep duration to reflect the communication patterns of the application

## ▶ Ideal

- ▶ Sleep whenever there is no data to receive from the base station
- ▶ Wake up for any incoming receptions

# Communication Device Suspension

---

## ▶ Problems

- ▶ How can a sender differentiate between a suspended node and a node that has gone away?
  - ▶ Suspended receiver  $\Rightarrow$  buffer packet
  - ▶ Confused sender  $\Rightarrow$  dropped packet, extra energy consumption
- ▶ How can a suspended node know there is communication for it?
  - ▶ Wake up too soon  $\Rightarrow$  waste energy
  - ▶ Wake up too late  $\Rightarrow$  delay/miss packets

# Communication Device Suspension

---

## ▶ Approach

- ▶ Ensure overlap between sender's and receiver's awake times

## ▶ Protocols

- ▶ Triggered Resume
- ▶ Periodic Resume
  - ▶ Synchronous
  - ▶ Asynchronous

# Triggered Resume

---

## ▶ Approach

- ▶ Use a second control channel (second radio)
  - ▶ Sender transmits RTS or beacon messages in control channel
  - ▶ Receiver replies in control channel and turns on main channel
- ▶ Main channel is only used for data
- ▶ Second channel
  - ▶ Must consume less energy than the main channel
  - ▶ Must not interfere with the main channel
  - ▶ Ex: BLE, ZigBee, RFID, 915Mhz

# Triggered Resume

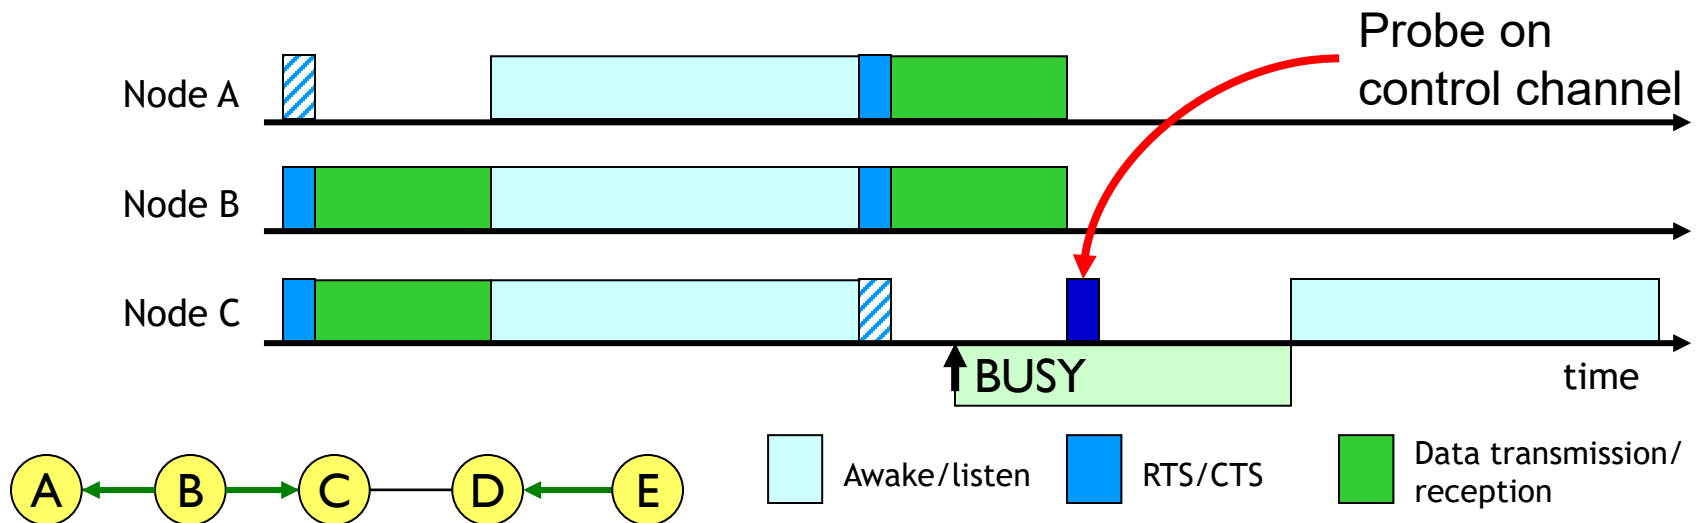

## ▶ Approach – Data only – PAMAS

### ▶ Data channel

- ▶ Power off radio when data is destined to a different node

### ▶ Control channel

- ▶ Probe neighbors to find longest remaining transfer

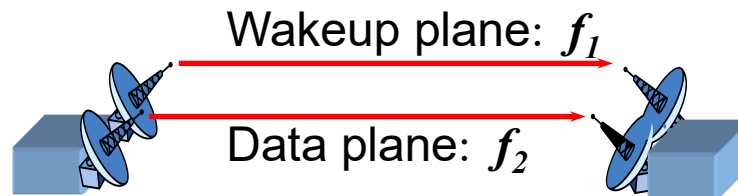

# Triggered Resume

---

## ▶ Dual radio

- ▶ Low duty cycle paging channel to wake up a neighboring node
- ▶ Use separate radio for the paging channel to avoid interference with regular data forwarding
- ▶ Trades off energy savings for setup latency

# Triggered Resume

## ► Dual radio

# Triggered Resume

---

## ▶ Challenges

- ▶ Two radios are more complex than one
- ▶ Channel characteristics may not be the same for both radios
  - ▶ A successful RTS on the control channel does not guarantee a the reverse channel works
  - ▶ A failed RTS on the control channel does not indicate that the reverse channel does not work

# Periodic Resume

---

## ▶ Approach

- ▶ Suspend most of the time
- ▶ Periodically resume to check for pending communication

## ▶ Communication indications

- ▶ Out-of-band channel
- ▶ In-band signaling

## ▶ Protocols

- ▶ Synchronous
- ▶ Asynchronous

# Synchronous Periodic Resume

---

## ▶ Basic Idea

- ▶ Time is slotted
- ▶ Nodes selectively remain awake for full slot duration
- ▶ Discovery occurs when two active slots overlap
- ▶ If all nodes are synchronized, all nodes are guaranteed to have overlapping awake periods

# Synchronous Periodic Resume

---

- ▶ **Protocol: IEEE 802.11 Power Save Mode (PSM)**
  - ▶ Nodes are synchronized and wakeup periodically (Beacon Period)
  - ▶ Each beacon period is broken up into two segments
    - ▶ Ad-hoc Traffic Indication Map (ATIM) Window
      - Announcement in the ATIM indicates data
      - Target node responds with an ATIM ACK
      - If a node receives no announcements, it goes back to sleep
    - ▶ Transmission period
      - Sender can transmit packet until the end of the beacon period

# Synchronous Periodic Resume

## ▶ IEEE 802.11 PSM

# Synchronous Periodic Resume

---

- ▶ **Centralized solution**

- ▶ Synchronization driven by base station
- ▶ In beacon message

- ▶ **Distributed solution**

- ▶ No base station
- ▶ Synchronization protocols can be used to loosely synchronize nodes
  - ▶ Nodes wake up for a short period and check for channel activity
  - ▶ Return to sleep if no activity detected

# Distributed Synchronous Periodic Resume

---

- ▶ Persistent loose synchronization
  - ▶ Constant, high synchronization overhead

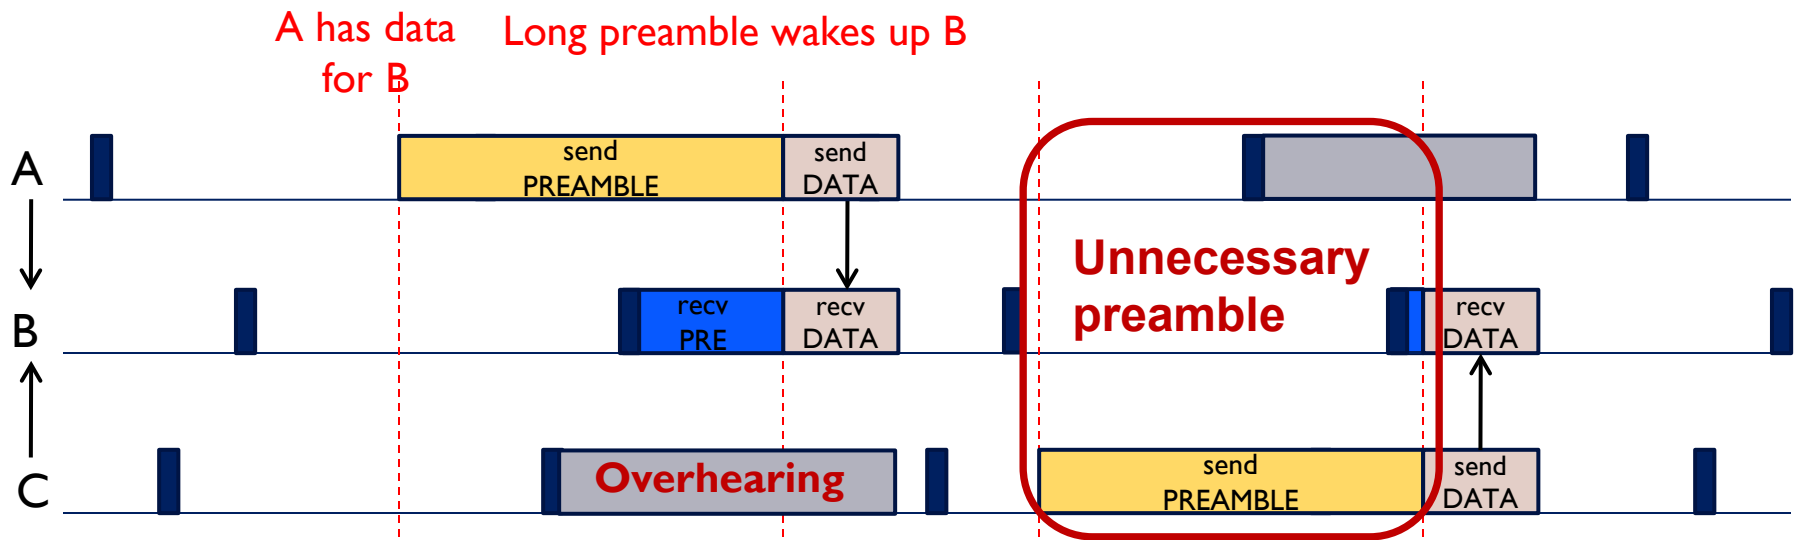

# Distributed Synchronous Periodic Resume

## ▶ Signaling

- ▶ No synchronization overhead
- ▶ High signaling overhead
  - ▶ Long preambles, all nodes wake up

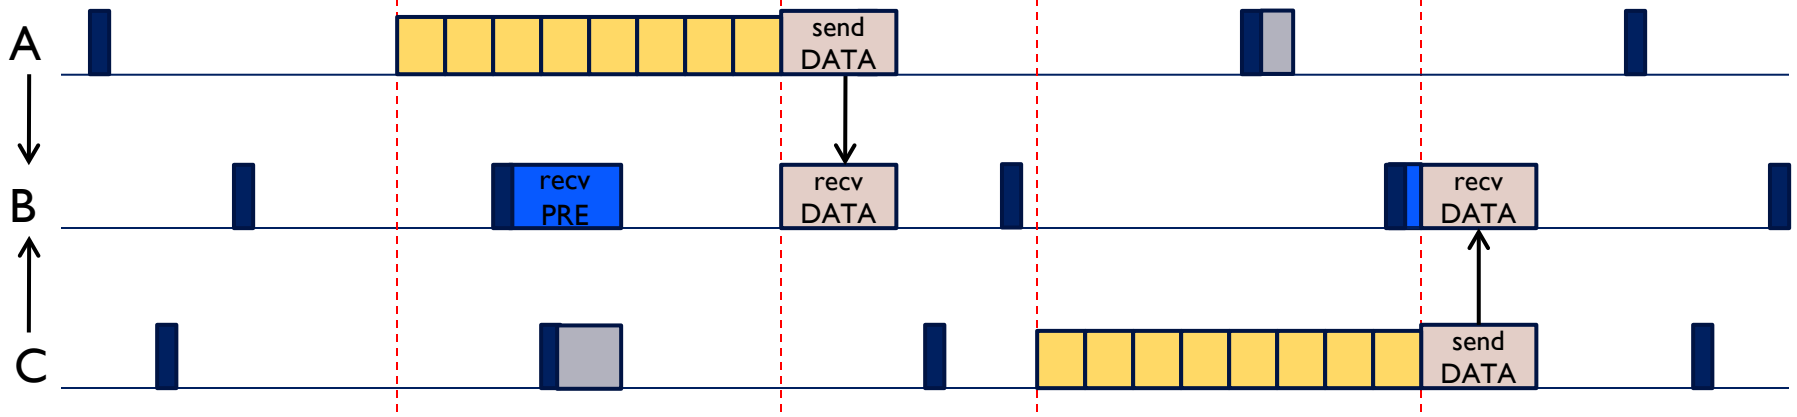

# Distributed Synchronous Periodic Resume

## ▶ Signaling: Wake-up packets

- ▶ Send wake-up packets instead of preamble
- ▶ Wake-up packets tell when data is starting so that receiver can go back to sleep as soon as it receives one wake-up packet

A has data  
for B

# Distributed Synchronous Periodic Resume

---

- ▶ **Signaling: Multiple send**
  - ▶ Send data several times
  - ▶ Receiver can listen at any time and get all data
  
- ▶ **Problem with all approaches**
  - ▶ Communication costs are mostly paid by the sender
  - ▶ The amount of time the sender spends transmitting may be much longer than the actual data length

# Synchronous Periodic Resume

---

## ▶ Problems

- ▶ Maintaining synchronization may be difficult
- ▶ Throughput is limited by the size of the notification window
  - ▶ If the notification window is too small, packets get buffered
  - ▶ Buffers may eventually overflow

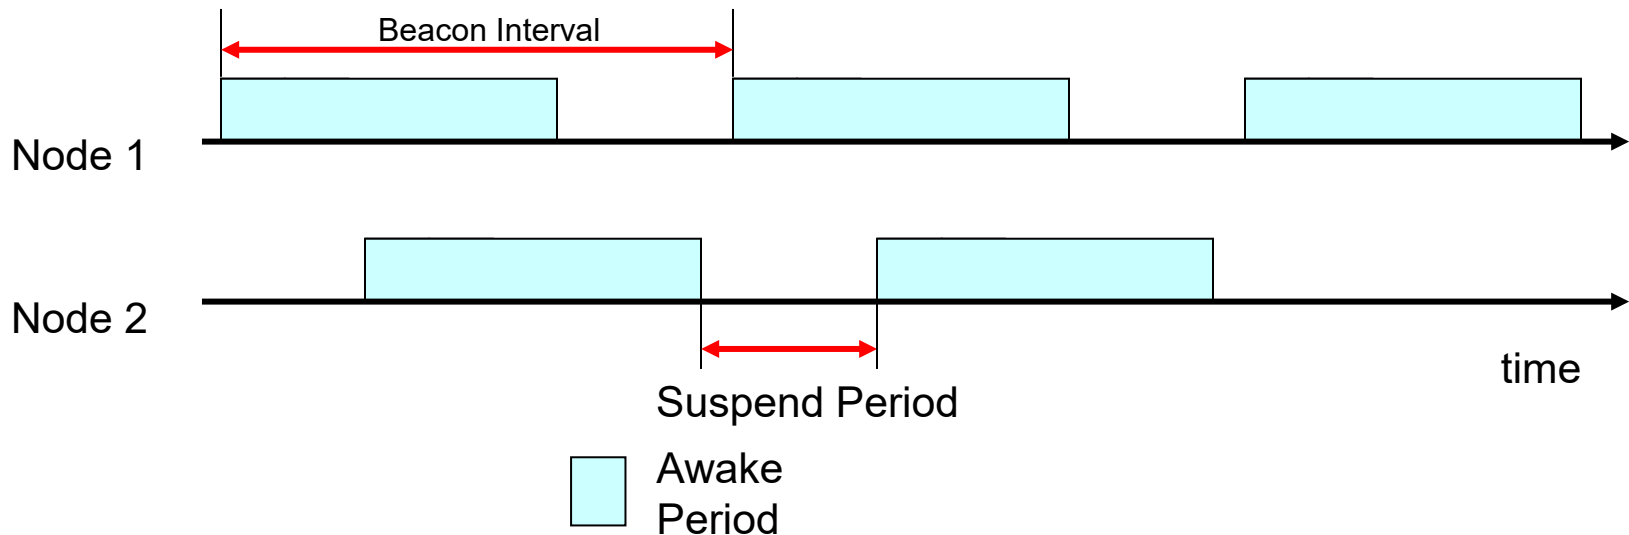

# Asynchronous Periodic Resume

---

## ► Approach

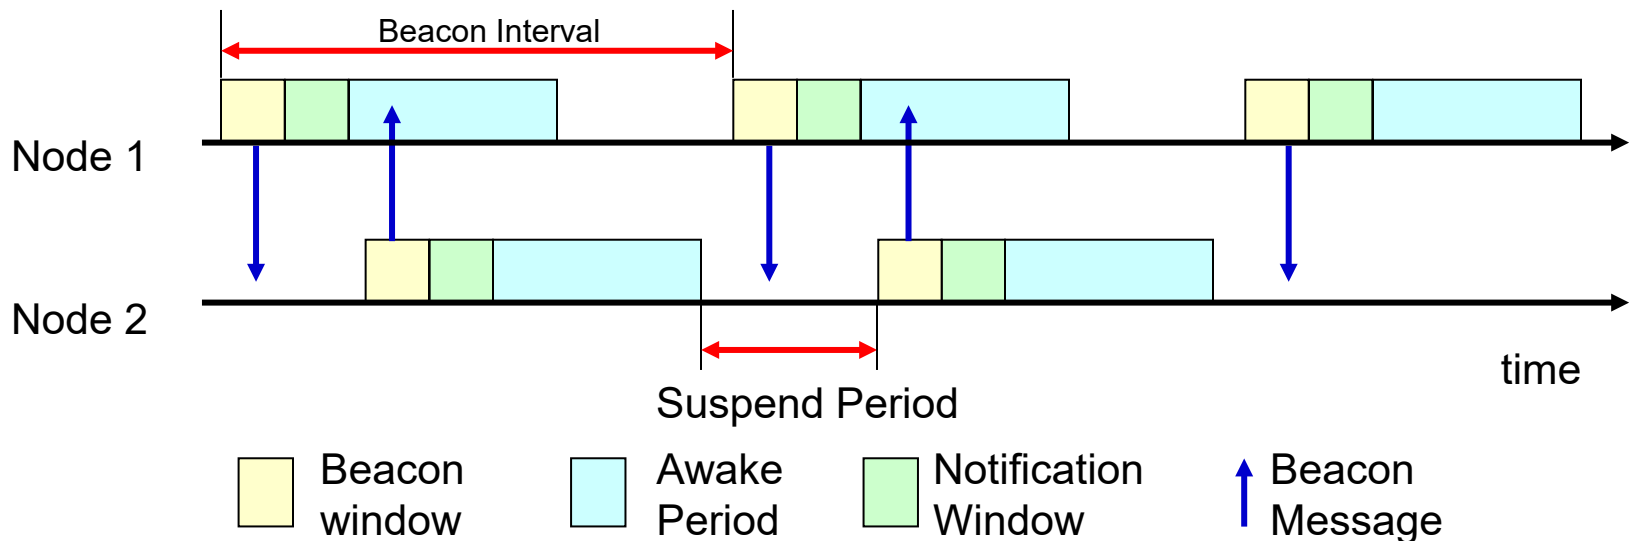

- Stay awake longer to guarantee overlap of awake periods
- Overlap is guaranteed if the awake periods are more than half the beacon period

# Asynchronous Periodic Resume

## ▶ Basic protocol

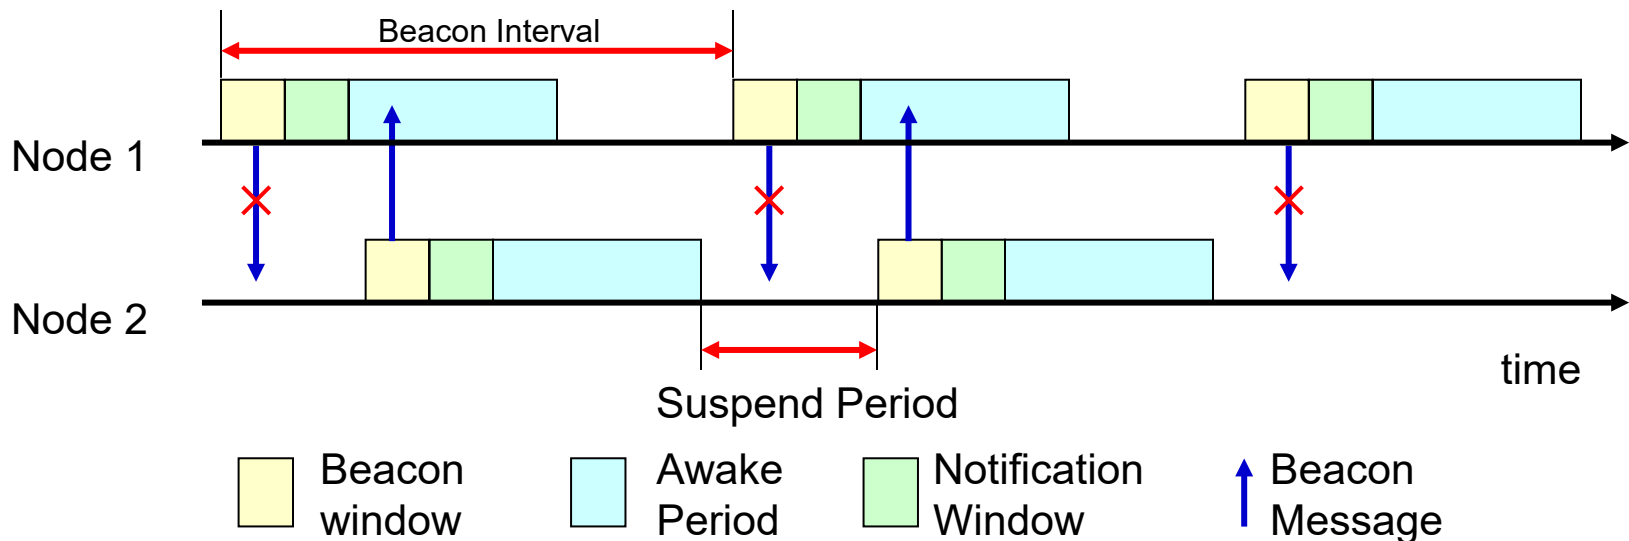

- ▶ Use beacon messages at the start of awake periods
- ▶ Some protocols use notification messages (similar to ATIM)

# Asynchronous Periodic Resume

## ► Problem

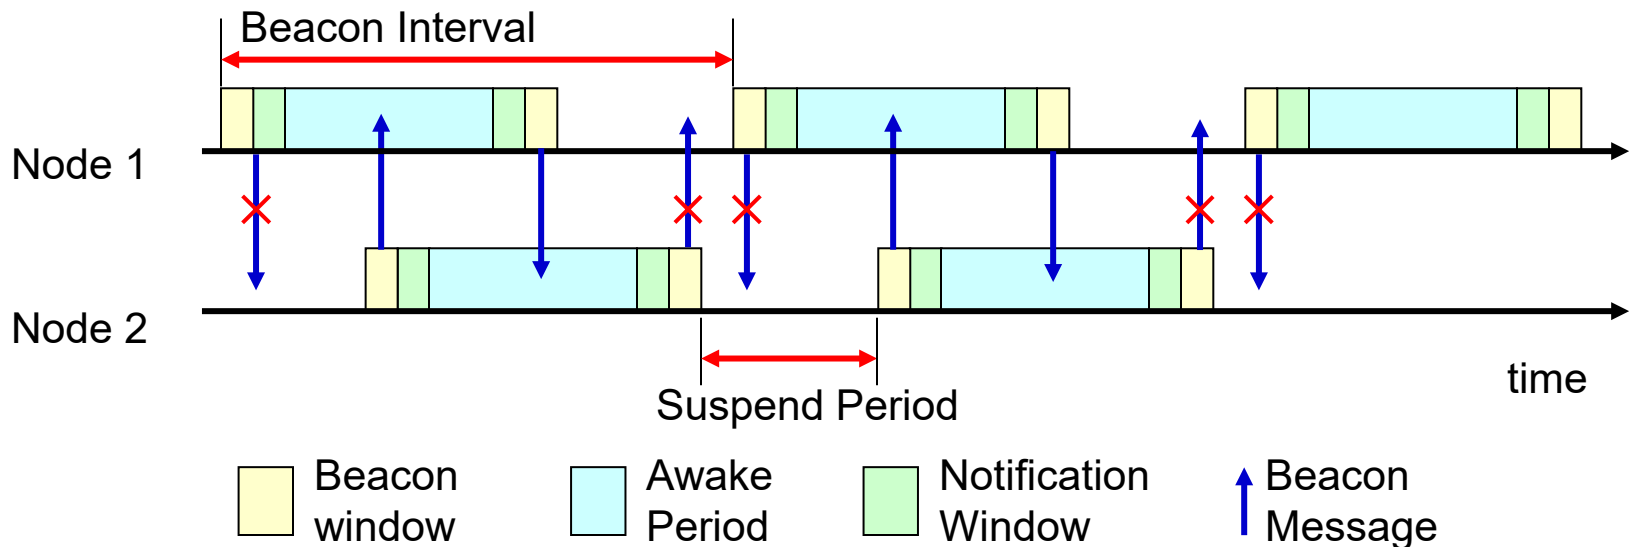

- No guarantee that all nodes will hear each other's beacon or notification messages

# Asynchronous Periodic Resume

## ► Solution

- Have a beacon at the beginning and end of the beacon interval

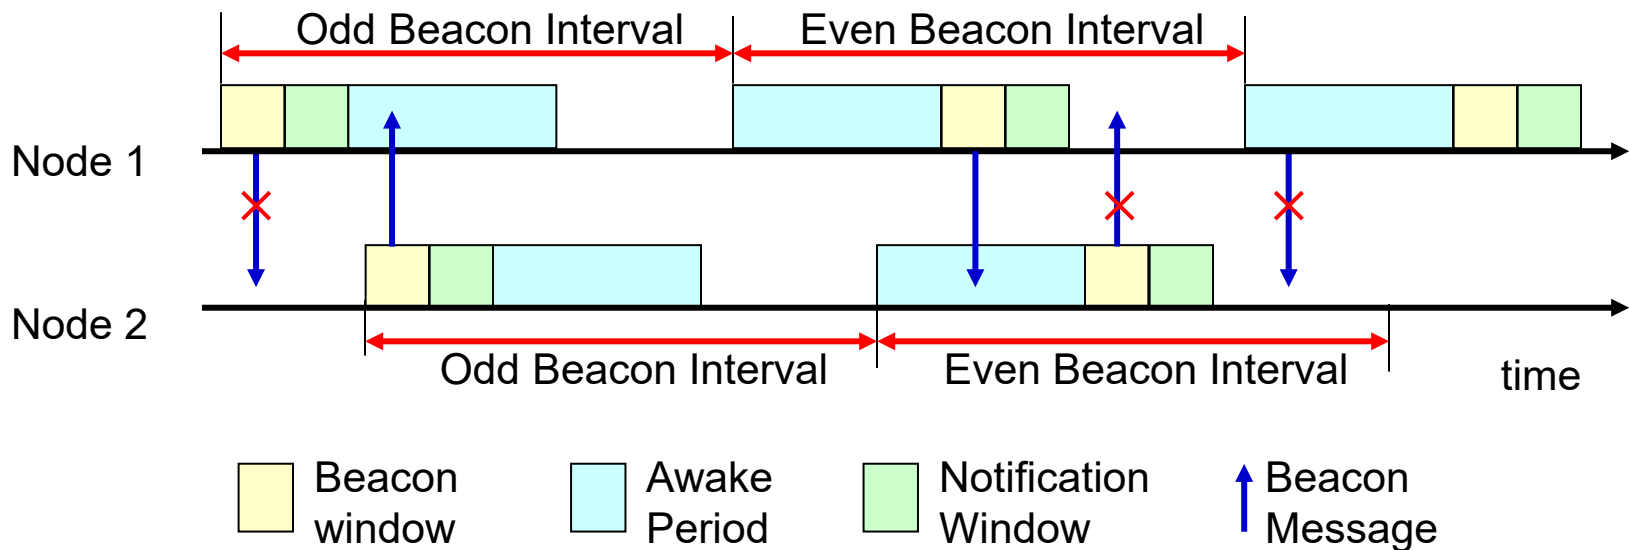

# Asynchronous Periodic Resume

## ▶ Alternate solution

- ▶ Beacon at the beginning of odd periods
- ▶ Beacon at the end of even periods

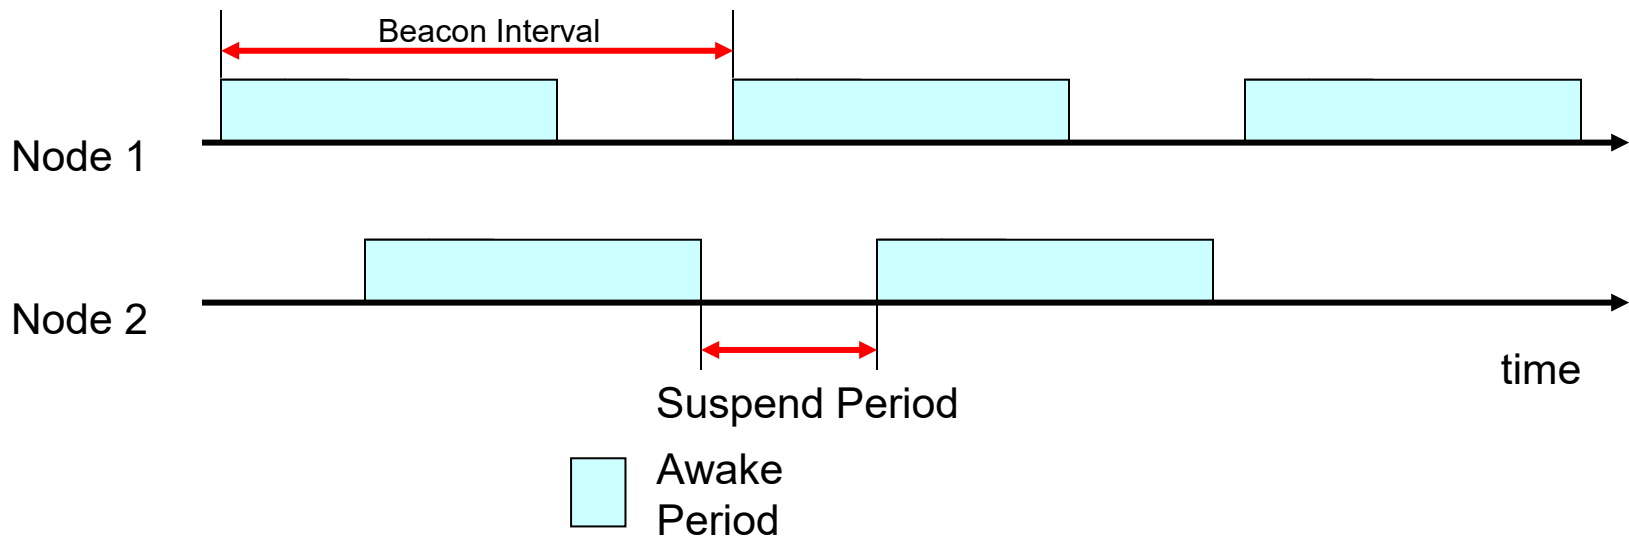

# Asynchronous Periodic Resume

---

## ▶ Problem

- ▶ Nodes stay awake more than half the time
- ▶ Wastes too much energy!

# Asynchronous Periodic Resume

- ▶ Reduce awake time
  - ▶ Do not wake up every beacon interval
  - ▶ Delay depends on number of overlapping intervals

# Asynchronous Periodic Resume

---

- ▶ Randomized Approach

- ▶ Birthday protocol

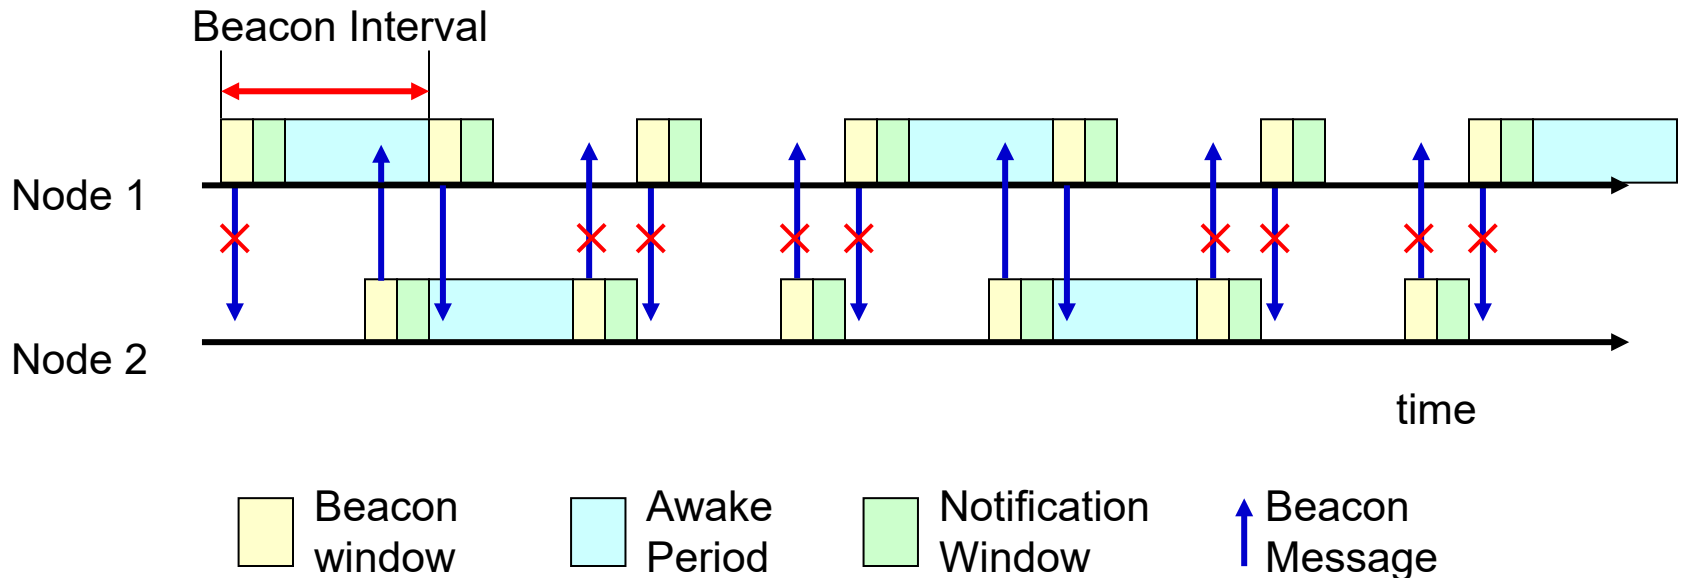

- ▶ Randomly select a slot to wake up in with a given probability
    - ▶ Advantage
      - Good average case performance
    - ▶ Disadvantage
      - No bounds on worst-case discovery latency

# Asynchronous Periodic Resume

## ▶ Extended sleep

- ▶ Wake up once every  $T$  intervals
- ▶ Adds delay up to  $T \times$  length of beacon interval

# Asynchronous Periodic Resume

---

## ▶ Quorum

- ▶ Increase number of beacon intervals in cycle ( $n$ )
- ▶ Increase number of awake periods ( $2n - 1$  of  $n^2$ )

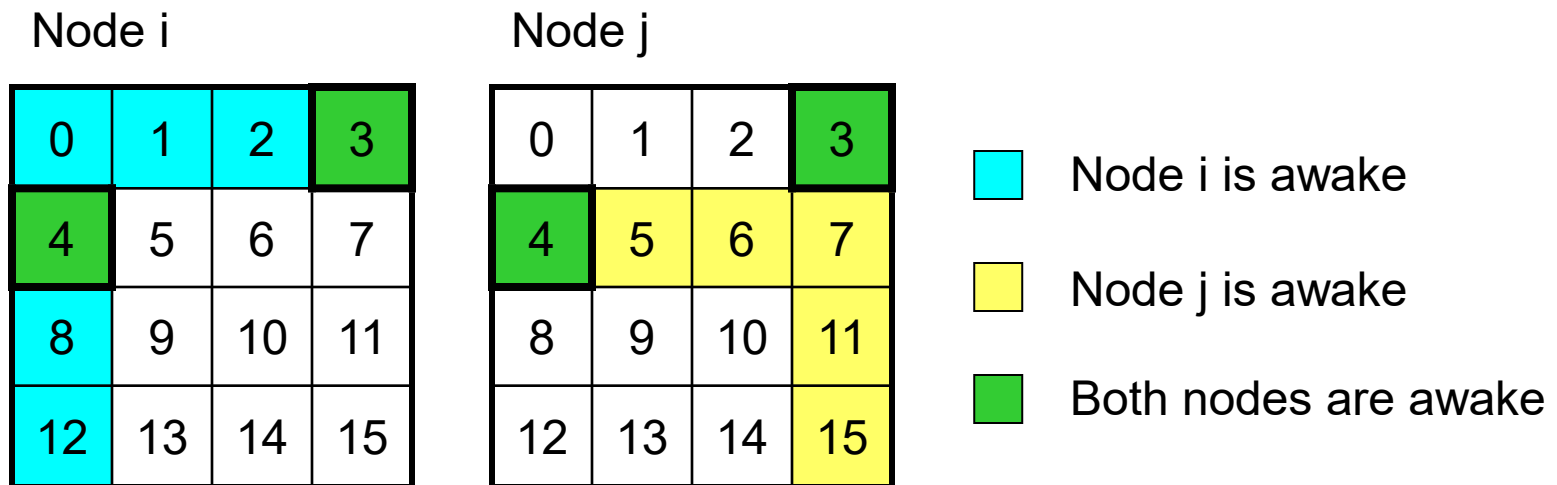

Delay is determined by where the overlap is (worst case  $n^2$ )

# Asynchronous Periodic Resume

---

## ▶ Quorum

- ▶ Example:  $n = 4$ ,  $n^2 = 16$ ,  $2n-1 = 7$ 
  - ▶ Two overlapping intervals: delay =  $n^2 - 2$

# Asynchronous Periodic Resume

---

## ▶ Deterministic

- ▶ Find a feasible overlapping pattern
  - ▶ Guarantee at least one overlapping interval
  - ▶ Requires knowledge of number of nodes

# Asynchronous Periodic Resume

---

- ▶ **Deterministic: Prime-based**
  - ▶ Disco
    - ▶ Pick two primes  $p_1$  and  $p_2$
    - ▶ Wake up every  $p_1$  and  $p_2$  slot
    - ▶ Guarantees discovery in  $p_1 \times p_2$  slots

# Asynchronous Periodic Resume

---

- ▶ **Deterministic: Prime-based**

- ▶ **U-Connect**

- ▶ Select 1 prime  $p$
    - ▶ Wake up every  $p$ th slot and  $(p-1)/2$  slots every  $p * p$  slots
    - ▶ Overlap is guaranteed within  $p^2$  slots

# Asynchronous Periodic Resume

---

## ▶ Searchlight

- ▶ Have a **deterministic** discovery schedule that has a **pseudo-random** component

# Asynchronous Periodic Resume

---

## ▶ Searchlight

- ▶ Two slots per  $t$  slots (period)
  - ▶ Anchor slot: Keep one slot fixed at slot 0
  - ▶ Probe slot: Move around the other slot sequentially
- ▶ Guaranteed overlap in  $t^*t/2$  slots
  - ▶ Based on the time needed to ensure a probe-anchor overlap
- ▶ Probe-probe overlap can also lead to discovery
  - ▶ Sequential scanning means less chance of a probe-probe overlap

Discovery through anchor-probe overlap

# Asynchronous Periodic Resume

---

## ▶ Searchlight

- ▶ Extension: randomized probing
  - ▶ Move the probe slot randomly
- ▶ Each node randomly chooses a schedule for its probe slot that repeats every  $(t \cdot t/2)$  slots
  - ▶ Schedules of two nodes appear random to each other
- ▶ Advantage
  - ▶ Retains the same worst-case bound
  - ▶ Improves average case performance

Discovery through probe-probe overlap

# Asynchronous Periodic Resume

---

## ▶ Challenges

- ▶ Reducing time spent awake
- ▶ Reducing delay
- ▶ No support for broadcast
  - ▶ None of the current approaches provide an interval where all nodes are awake
