## Part I

# Exponentiation, Binary Search

# Exponentiation

**Input** Two numbers:  $a$  and integer  $n \geq 0$

**Goal** Compute  $a^n$

# Exponentiation

**Input** Two numbers:  $a$  and integer  $n \geq 0$

**Goal** Compute  $a^n$

Obvious algorithm:

SlowPow(a,n):

```
x = 1;
for i = 1 to n do
    x = x*a
Output x
```

$O(n)$  multiplications.

# Fast Exponentiation

**Observation:**  $a^n = a^{\lfloor n/2 \rfloor} a^{\lceil n/2 \rceil} = a^{\lfloor n/2 \rfloor} a^{\lfloor n/2 \rfloor} a^{\lceil n/2 \rceil - \lfloor n/2 \rfloor}$ .

# Fast Exponentiation

**Observation:**  $a^n = a^{\lfloor n/2 \rfloor} a^{\lceil n/2 \rceil} = a^{\lfloor n/2 \rfloor} a^{\lfloor n/2 \rfloor} a^{\lceil n/2 \rceil - \lfloor n/2 \rfloor}$ .

```
FastPow(a,n):  
    if (n = 0) return 1  
    x = FastPow(a, ⌊n/2⌋)  
    x = x*x  
    if (n is odd)  
        x = x*a  
    return x
```

# Fast Exponentiation

**Observation:**  $a^n = a^{\lfloor n/2 \rfloor} a^{\lceil n/2 \rceil} = a^{\lfloor n/2 \rfloor} a^{\lfloor n/2 \rfloor} a^{\lceil n/2 \rceil - \lfloor n/2 \rfloor}$ .

```
FastPow(a,n):  
    if (n = 0) return 1  
    x = FastPow(a, ⌊n/2⌋)  
    x = x*x  
    if (n is odd)  
        x = x*a  
    return x
```

$T(n)$ : number of multiplications for  $n$

# Fast Exponentiation

**Observation:**  $a^n = a^{\lfloor n/2 \rfloor} a^{\lceil n/2 \rceil} = a^{\lfloor n/2 \rfloor} a^{\lfloor n/2 \rfloor} a^{\lceil n/2 \rceil - \lfloor n/2 \rfloor}$ .

```
FastPow(a,n):  
  if (n = 0) return 1  
  x = FastPow(a, ⌊n/2⌋)  
  x = x*x  
  if (n is odd)  
    x = x*a  
  return x
```

$T(n)$ : number of multiplications for  $n$

$$T(n) \leq T(\lfloor n/2 \rfloor) + 2$$

$T(n) =$

# Fast Exponentiation

**Observation:**  $a^n = a^{\lfloor n/2 \rfloor} a^{\lceil n/2 \rceil} = a^{\lfloor n/2 \rfloor} a^{\lfloor n/2 \rfloor} a^{\lceil n/2 \rceil - \lfloor n/2 \rfloor}$ .

```
FastPow(a,n):  
  if (n = 0) return 1  
  x = FastPow(a, ⌊n/2⌋)  
  x = x*x  
  if (n is odd)  
    x = x*a  
  return x
```

$T(n)$ : number of multiplications for  $n$

$$T(n) \leq T(\lfloor n/2 \rfloor) + 2$$

$$T(n) = \Theta(\log n).$$

# Complexity of Exponentiation

**Question:** Is SlowPow() a polynomial time algorithm? FastPow?

# Complexity of Exponentiation

**Question:** Is SlowPow() a polynomial time algorithm? FastPow?

Input size:  $\log a + \log n$

# Complexity of Exponentiation

**Question:** Is SlowPow() a polynomial time algorithm? FastPow?

Input size:  $\log a + \log n$

Output size:

# Complexity of Exponentiation

**Question:** Is SlowPow() a polynomial time algorithm? FastPow?

Input size:  $\log a + \log n$

Output size:  $n \log a$ . Not necessarily polynomial in input size!

Both SlowPow and FastPow are polynomial in output size.

# Exponentiation modulo a given number

Exponentiation in applications:

**Input** Three integers:  $a$ ,  $n \geq 0$ ,  $p \geq 2$  (typically a prime)

**Goal** Compute  $a^n \pmod p$

# Exponentiation modulo a given number

Exponentiation in applications:

**Input** Three integers:  $a$ ,  $n \geq 0$ ,  $p \geq 2$  (typically a prime)

**Goal** Compute  $a^n \pmod p$

Input size:  $\Theta(\log a + \log n + \log p)$

Output size:  $O(\log p)$  and hence polynomial in input size.

# Exponentiation modulo a given number

Exponentiation in applications:

**Input** Three integers:  $a$ ,  $n \geq 0$ ,  $p \geq 2$  (typically a prime)

**Goal** Compute  $a^n \pmod p$

Input size:  $\Theta(\log a + \log n + \log p)$

Output size:  $O(\log p)$  and hence polynomial in input size.

**Observation:**  $xy \pmod p = ((x \pmod p)(y \pmod p)) \pmod p$

# Exponentiation modulo a given number

**Input** Three integers:  $a$ ,  $n \geq 0$ ,  $p \geq 2$  (typically a prime)

**Goal** Compute  $a^n \bmod p$

```
FastPowMod(a,n,p):  
  if (n = 0) return 1  
  x = FastPowMod(a, [n/2], p)  
  x = x*x mod p  
  if (n is odd)  
    x = x*a mod p  
  return x
```

# Exponentiation modulo a given number

**Input** Three integers:  $a$ ,  $n \geq 0$ ,  $p \geq 2$  (typically a prime)

**Goal** Compute  $a^n \bmod p$

```
FastPowMod(a,n,p):  
  if (n = 0) return 1  
  x = FastPowMod(a, [n/2], p)  
  x = x*x mod p  
  if (n is odd)  
    x = x*a mod p  
  return x
```

FastPowMod is a polynomial time algorithm. SlowPowMod is not (why?).

# Binary Search in Sorted Arrays

**Input** Sorted array  $A$  of  $n$  numbers and number  $x$

**Goal** Is  $x$  in  $A$ ?

# Binary Search in Sorted Arrays

**Input** Sorted array  $A$  of  $n$  numbers and number  $x$

**Goal** Is  $x$  in  $A$ ?

```
BinarySearch(A[a..b], x):  
  if (b-a <= 0) return NO  
  mid = A[[(a + b)/2]]  
  if (x = mid) return YES  
  else if (x < mid) return BinarySearch(A[a..[(a + b)/2] - 1], x)  
  else return BinarySearch(A[[(a + b)/2] + 1..b], x)
```

# Binary Search in Sorted Arrays

**Input** Sorted array  $A$  of  $n$  numbers and number  $x$

**Goal** Is  $x$  in  $A$ ?

```
BinarySearch(A[a..b], x):  
  if (b-a <= 0) return NO  
  mid = A[[(a + b)/2]]  
  if (x = mid) return YES  
  else if (x < mid) return BinarySearch(A[a..[(a + b)/2] - 1], x)  
  else return BinarySearch(A[[(a + b)/2] + 1..b], x)
```

Analysis:  $T(n) = T(\lfloor n/2 \rfloor) + O(1)$ .  $T(n) = O(\log n)$ .

**Observation:** After  $k$  steps, size of array left is  $n/2^k$

# Another common use of binary search

- **Optimization version:** find solution of best (say minimum) value
- **Decision version:** is there a solution of value at most a given value  $v$ ?

## Another common use of binary search

- **Optimization version:** find solution of best (say minimum) value
- **Decision version:** is there a solution of value at most a given value  $v$ ?

Reduce optimization to decision (may be easier to think about):

- Given instance  $I$  compute upper bound  $U(I)$  on best value
- Compute lower bound  $L(I)$  on best value
- Do binary search on interval  $[L(I), U(I)]$  using decision version as black box
- $O(\log(U(I) - L(I)))$  calls to decision version if  $U(I), L(I)$  are integers

# Example

- **Problem:** shortest paths in a graph.
- **Decision version:** given  $G$  with non-negative integer edge lengths, nodes  $s, t$  and bound  $B$ , is there an  $s-t$  path in  $G$  of length at most  $B$ ?
- **Optimization version:** find the length of a shortest path between  $s$  and  $t$  in  $G$ .

**Question:** given a black box algorithm for the decision version, can we obtain an algorithm for the optimization version?

## Example continued

**Question:** given a black box algorithm for the decision version, can we obtain an algorithm for the optimization version?

- Let  $U$  be maximum edge length in  $G$ .
- Minimum edge length is  $L$ .
- $s$ - $t$  shortest path length is at most  $(n - 1)U$  and at least  $L$ .
- Apply binary search on the interval  $[L, (n - 1)U]$  via the algorithm for the decision problem.
- $O(\log((n - 1)U - L))$  calls to the decision problem algorithm sufficient. Polynomial in input size.

## Part II

# Introduction to Dynamic Programming

# Recursion

Reduction: reduce one problem to another

Recursion: a special case of reduction

- reduce problem to a *smaller* instance of *itself*
- self-reduction

# Recursion

Reduction: reduce one problem to another

Recursion: a special case of reduction

- reduce problem to a *smaller* instance of *itself*
- self-reduction
- Problem instance of size  $n$  is reduced to one or more instances of size  $n - 1$  or less.
- For termination, problem instances of small size are solved by some other method as *base cases*

# Recursion in Algorithm Design

- **Tail Recursion:** problem reduced to a *single* recursive call after some work. Easy to convert algorithm into iterative or greedy algorithms. Examples: Interval scheduling, MST algorithms, etc.
- **Divide and Conquer:** problem reduced to multiple *independent* sub-problems that are solved separately. Conquer step puts together solution for bigger problem.
- **Dynamic Programming:** problem reduced to multiple (typically) *dependent or overlapping* sub-problems. Use *memoization* to avoid recomputation of common solutions leading to *iterative bottom-up* algorithm.

# Fibonacci Numbers

Fibonacci numbers defined by recurrence:

$$F(n) = F(n-1) + F(n-2) \text{ and } F(0) = 0, F(1) = 1.$$

These numbers have many interesting and amazing properties.  
A journal *The Fibonacci Quarterly!*

- $F(n) = (\phi^n - (1 - \phi)^n) / \sqrt{5}$  where  $\phi$  is the golden ratio  $(1 + \sqrt{5})/2 \simeq 1.618$ .
- $\lim_{n \rightarrow \infty} F(n+1)/F(n) = \phi$

# Fibonacci Numbers

Fibonacci numbers defined by recurrence:

$$F(n) = F(n-1) + F(n-2) \text{ and } F(0) = 0, F(1) = 1.$$

These numbers have many interesting and amazing properties.  
A journal *The Fibonacci Quarterly!*

- $F(n) = (\phi^n - (1 - \phi)^n) / \sqrt{5}$  where  $\phi$  is the golden ratio  $(1 + \sqrt{5})/2 \simeq 1.618$ .
- $\lim_{n \rightarrow \infty} F(n+1)/F(n) = \phi$

**Question:** Given  $n$ , compute  $F(n)$ .

# Recursive Algorithm for Fibonacci Numbers

```
Fib(n):  
    if (n = 0)  
        return 0  
    else if (n = 1)  
        return 1  
    else  
        return Fib(n-1) + Fib(n-2)
```

# Recursive Algorithm for Fibonacci Numbers

```
Fib(n):  
  if (n = 0)  
    return 0  
  else if (n = 1)  
    return 1  
  else  
    return Fib(n-1) + Fib(n-2)
```

Running time? Let  $T(n)$  be the number of additions in  $\text{Fib}(n)$ .

# Recursive Algorithm for Fibonacci Numbers

```

Fib(n):
  if (n = 0)
    return 0
  else if (n = 1)
    return 1
  else
    return Fib(n-1) + Fib(n-2)

```

Running time? Let  $T(n)$  be the number of additions in  $\text{Fib}(n)$ .

$$T(n) = T(n-1) + T(n-2) + 1 \text{ and } T(0) = T(1) = 0$$

Roughly same as  $F(n)$

$$T(n) = \Theta(\phi^n)$$

The number of additions is exponential in  $n$ .

# Recursive Algorithm for Fibonacci Numbers

```
Fib(n):  
  if (n = 0)  
    return 0  
  else if (n = 1)  
    return 1  
  else  
    return Fib(n-1) + Fib(n-2)
```

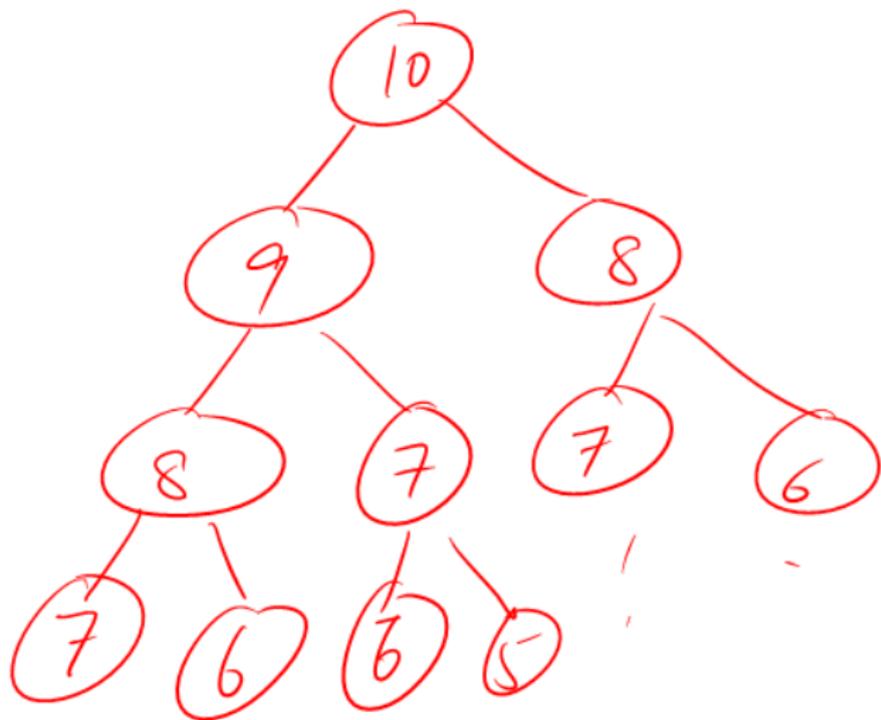

Running time? Let  $T(n)$  be the number of additions in Fib( $n$ ).

$$T(n) = T(n-1) + T(n-2) + 1 \text{ and } T(0) = T(1) = 0$$

Roughly same as  $F(n)$

$$T(n) = \Theta(\phi^n)$$

The number of additions is exponential in  $n$ . Can we do better?

# An iterative algorithm for Fibonacci numbers

```
Fib(n):  
  if (n = 0)  
    return 0  
  else if (n = 1)  
    return 1  
  else  
    F[0] = 0  
    F[1] = 1  
    for i = 2 to n do  
      F[i] = F[i-1] + F[i-2]  
    return F[n]
```

# An iterative algorithm for Fibonacci numbers

```
Fib(n):  
  if (n = 0)  
    return 0  
  else if (n = 1)  
    return 1  
  else  
    F[0] = 0  
    F[1] = 1  
    for i = 2 to n do  
      F[i] = F[i-1] + F[i-2]  
    return F[n]
```

What is the running time of the algorithm?

# An iterative algorithm for Fibonacci numbers

```
Fib(n):  
  if (n = 0)  
    return 0  
  else if (n = 1)  
    return 1  
  else  
    F[0] = 0  
    F[1] = 1  
    for i = 2 to n do  
      F[i] = F[i-1] + F[i-2]  
    return F[n]
```

What is the running time of the algorithm?  $O(n)$  additions.

# What is the difference?

- Recursive algorithm is computing the same numbers again and again.
- Iterative algorithm is storing computed values and building bottom up the final value.

# What is the difference?

- Recursive algorithm is computing the same numbers again and again.
- Iterative algorithm is storing computed values and building bottom up the final value. **Memoization**.

# What is the difference?

- Recursive algorithm is computing the same numbers again and again.
- Iterative algorithm is storing computed values and building bottom up the final value. **Memoization.**

Dynamic Programming: finding a recursion that can be *effectively/efficiently* memoized

Leads to polynomial time algorithm if number of sub-problems is polynomial in input size.

# Automatic Memoization

Can we convert recursive algorithm into an efficient algorithm without explicitly doing an iterative algorithm?

# Automatic Memoization

Can we convert recursive algorithm into an efficient algorithm without explicitly doing an iterative algorithm?

```
Fib(n):  
  if (n = 0)  
    return 0  
  else if (n = 1)  
    return 1  
  else if (Fib(n) was previously computed)  
    return stored value of Fib(n)  
  else  
    return Fib(n-1) + Fib(n-2)
```

# Automatic Memoization

Can we convert recursive algorithm into an efficient algorithm without explicitly doing an iterative algorithm?

```
Fib(n):  
    if (n = 0)  
        return 0  
    else if (n = 1)  
        return 1  
    else if (Fib(n) was previously computed)  
        return stored value of Fib(n)  
    else  
        return Fib(n-1) + Fib(n-2)
```

How do we keep track of previously computed values?

# Automatic Memoization

Can we convert recursive algorithm into an efficient algorithm without explicitly doing an iterative algorithm?

```
Fib(n):  
    if (n = 0)  
        return 0  
    else if (n = 1)  
        return 1  
    else if (Fib(n) was previously computed)  
        return stored value of Fib(n)  
    else  
        return Fib(n-1) + Fib(n-2)
```

How do we keep track of previously computed values?

Two methods: explicitly and implicitly (via data structure)

# Automatic explicit memoization

Initialize table/array  $M$  of size  $n$  such that  $M[i] = -1$  for  $0 \leq i < n$

# Automatic explicit memoization

Initialize table/array  $M$  of size  $n$  such that  $M[i] = -1$  for  $0 \leq i < n$

Fib( $n$ ):

```
if (n = 0)
    return 0
else if (n = 1)
    return 1
else if (M[n]  $\neq$  -1) (* M[n] has stored value of Fib(n) *)
    return M[n]
else
    M[n] = Fib(n-1) + Fib(n-2)
    return M[n]
```

Need to know upfront the number of subproblems to allocate memory

# Automatic implicit memoization

Initialize a (dynamic) dictionary data structure  $D$  to empty

```
Fib(n):  
    if (n = 0)  
        return 0  
    else if (n = 1)  
        return 1  
    else if (n is already in D)  
        return value stored with n in D  
    else  
        val = Fib(n-1) + Fib(n-2)  
        Store (n, val) in D  
        return val
```

# Explicit vs Implicit Memoization

- Explicit memoization or iterative algorithm preferred if one can analyze problem ahead of time. Allows for efficient memory allocation and access.
- Implicit and automatic memoization used when problem structure or algorithm is either not well understood or in fact unknown to the underlying system
  - need to pay overhead of datastructure
  - Functional languages such as LISP automatically do memoization, usually via hashing based dictionaries.

# Back to Fibonacci Numbers

Is the iterative algorithm a *polynomial* time algorithm? Does it take  $O(n)$  time?

# Back to Fibonacci Numbers

Is the iterative algorithm a *polynomial* time algorithm? Does it take  $O(n)$  time?

- input is  $n$  and hence input size is  $\Theta(\log n)$

# Back to Fibonacci Numbers

Is the iterative algorithm a *polynomial* time algorithm? Does it take  $O(n)$  time?

- input is  $n$  and hence input size is  $\Theta(\log n)$
- output is  $F(n)$  and output size is  $\Theta(n)$ . Why?

# Back to Fibonacci Numbers

Is the iterative algorithm a *polynomial* time algorithm? Does it take  $O(n)$  time?

- input is  $n$  and hence input size is  $\Theta(\log n)$
- output is  $F(n)$  and output size is  $\Theta(n)$ . Why?
- Hence output size is exponential in input size so no polynomial time algorithm possible!

# Back to Fibonacci Numbers

Is the iterative algorithm a *polynomial* time algorithm? Does it take  $O(n)$  time?

- input is  $n$  and hence input size is  $\Theta(\log n)$
- output is  $F(n)$  and output size is  $\Theta(n)$ . Why?
- Hence output size is exponential in input size so no polynomial time algorithm possible!
- Running time of iterative algorithm:  $\Theta(n)$  additions but number sizes are  $O(n)$  bits long! Hence total time is  $O(n^2)$ , in fact  $\Theta(n^2)$ . Why?

# Back to Fibonacci Numbers

Is the iterative algorithm a *polynomial* time algorithm? Does it take  $O(n)$  time?

- input is  $n$  and hence input size is  $\Theta(\log n)$
- output is  $F(n)$  and output size is  $\Theta(n)$ . Why?
- Hence output size is exponential in input size so no polynomial time algorithm possible!
- Running time of iterative algorithm:  $\Theta(n)$  additions but number sizes are  $O(n)$  bits long! Hence total time is  $O(n^2)$ , in fact  $\Theta(n^2)$ . Why?
- Running time of recursive algorithm is  $O(n\phi^n)$  but can in fact shown to be  $O(\phi^n)$  by being careful. Doubly exponential in input size and exponential even in output size.

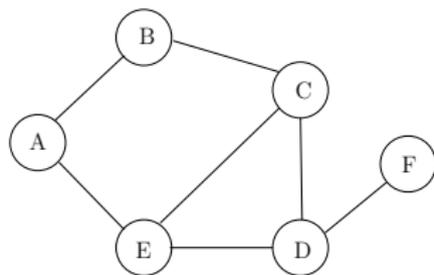

## Part III

# Brute Force Search, Recursion and Backtracking

# Maximum Independent Set in a Graph

## Definition

Given undirected graph  $G = (V, E)$  a subset of nodes  $S \subseteq V$  is an **independent set** (also called a stable set) if for there are no edges between nodes in  $S$ . That is, if  $u, v \in S$  then  $(u, v) \notin E$ .

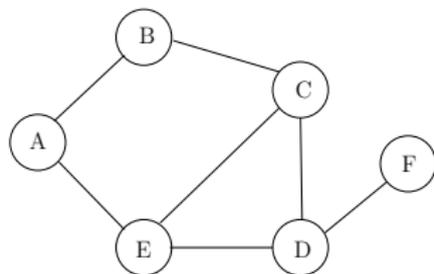

Some independent sets in graph above:  $\{E, F\}$ ,  $\{A, C, F\}$ ,

# Maximum Independent Set Problem

**Input** Graph  $G = (V, E)$

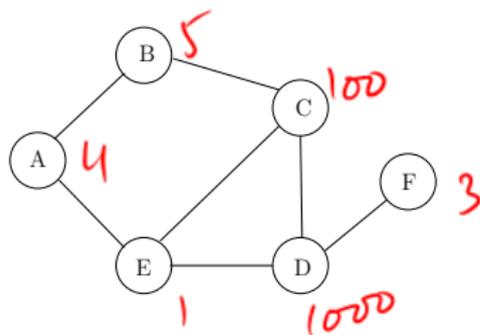

**Goal** Find maximum sized independent set in  $G$

# Maximum Weight Independent Set Problem

**Input** Graph  $G = (V, E)$ , weights  $w(v) \geq 0$  for  $v \in V$

**Goal** Find maximum weight independent set in  $G$

# Maximum Weight Independent Set Problem

- No one knows an *efficient* (polynomial time) algorithm for this problem
- Problem is NP-Complete and it is *believed* that there is no polynomial time algorithm

A *brute-force* algorithm: try all subsets of vertices.

# Brute-force enumeration

Algorithm to find the size of the maximum weight independent set.

MaxIndSet( $G = (V, E)$ ):

$max = 0$

for each subset  $S \subseteq V$

    check if  $S$  is an independent set

    if  $S$  is an independent set and  $w(S) > max$

$max = w(S)$

    endfor

Output  $max$

# Brute-force enumeration

Algorithm to find the size of the maximum weight independent set.

MaxIndSet( $G = (V, E)$ ):

$max = 0$

    for each subset  $S \subseteq V$

        check if  $S$  is an independent set

        if  $S$  is an independent set and  $w(S) > max$

$max = w(S)$

    endfor

Output  $max$

Running time: suppose  $G$  has  $n$  vertices and  $m$  edges

- $2^n$  subsets of  $V$
- checking each subset  $S$  takes  $O(m)$  time
- total time is  $O(m2^n)$

# A Recursive Algorithm

Let  $V = \{v_1, v_2, \dots, v_n\}$ .

For a vertex  $u$  let  $N(u)$  be its neighbours.

# A Recursive Algorithm

Let  $V = \{v_1, v_2, \dots, v_n\}$ .

For a vertex  $u$  let  $N(u)$  be its neighbours.

## Observation

*One of the following two cases is true*

**Case 1**  $v_n$  is in some maximum independent set.

**Case 2**  $v_n$  is in no maximum independent set.

# A Recursive Algorithm

Let  $V = \{v_1, v_2, \dots, v_n\}$ .

For a vertex  $u$  let  $N(u)$  be its neighbours.

## Observation

*One of the following two cases is true*

**Case 1**  $v_n$  is in some maximum independent set.

**Case 2**  $v_n$  is in no maximum independent set.

Recursive-MIS( $G$ ):

If  $G$  is empty, Output 0

$a = \text{Recursive-MIS}(G - v_n)$

$b = w(v_n) + \text{Recursive-MIS}(G - v_n - N(v_n))$

Output  $\max(a, b)$

# Recursive Algorithms of MIS

Running time:

$$T(n) =$$

# Recursive Algorithms of MIS

Running time:

$$T(n) = T(n - 1) + T(n - 1 - \text{deg}(v_1)) + O(1)$$

where  $\text{deg}(v_1)$  is the degree of  $v_1$ .  $T(0) = T(1) = 1$  is base case.

Worst case is when  $\text{deg}(v_1) = 0$  when the recurrence becomes

$$T(n) = 2T(n - 1) + O(1)$$

Solution to this is  $T(n) = O(2^n)$ .

# Backtrack Search via Recursion

- Recursive algorithm generates a tree of computation where each node is a smaller problem (subproblem)
- Simple recursive algorithm computes/explores the whole tree blindly in some order.
- Backtrack search is a way to explore the tree intelligently to prune the search space
  - Some subproblems may be so simple that we can stop the recursive algorithm and solve it directly by some other method
  - Memoization to avoid recomputing same problem
  - Stop recursing at a subproblem if it is clear that there is no need to explore further.
  - Leads to a number of heuristics that are widely used in practice although the worst case running time may still be exponential.

# Example
