

Appendix 3 to Lecture 21: Two Symbolic Methods to prove Deadlock Freedom

J. Meseguer

Call an admissible rewrite theory $\mathcal{R} = (\Sigma, E \cup B, R)$ with constructor signature Ω *never terminating* iff it has no deadlocks, i.e., iff for each $t \in T_\Omega$ in \vec{E} , B -canonical form there always exists a $t' \in T_\Sigma$ such that $t \rightarrow_{R/B} t'$. This notion suggests two methods to symbolically prove that a topmost rewrite theory of the form $\mathcal{R} = (\Sigma, B, R)$ satisfies the deadlock freedom invariant from a symbolic initial state $u_1 \vee \dots \vee u_n$:

Method 1: Check the Never Terminating Property Automatically

Obviously, if $\mathcal{R} = (\Sigma, B, R)$ is never terminating, it will automatically satisfy the deadlock freedom invariant from *any* symbolic initial state $u_1 \vee \dots \vee u_n$. If the rules $(l \rightarrow r) \in R$ are all *left-linear*, i.e., each variable x in l appears at a single position p in l , checking whether \mathcal{R} is never terminating becomes decidable, since it reduces to checking that if $R = \{l_i \rightarrow r_i \mid 1 \leq i \leq k\}$, then the set $\{l_i \mid 1 \leq i \leq k\}$ is a *generator set* for the topmost sort *State* of \mathcal{R} . But this, as explained in pg. 18 of Lecture 15, can be automatically decided by the SCC tool by checking the sufficient completeness of the Maude functional module defining the *sort predicate* $State : State \rightarrow Bool$ associated to supposed generator set $\{l_i \mid 1 \leq i \leq k\}$.

Since \mathcal{R} satisfying the deadlock free invariant from a symbolic initial state $u_1 \vee \dots \vee u_n$ is a *weaker property* than \mathcal{R} being never terminating (since the invariant only involves states reachable from $u_1 \vee \dots \vee u_n$), the above automatic SCC check may fail (so that \mathcal{R} fails to be never terminating), whereas the deadlock free invariant may still hold for some symbolic initial state $u_1 \vee \dots \vee u_n$. What can we do in this case? Several things. But, first of all, note that if the SCC test fails, then the SCC tool will give us a *ground term counterexample* of the form: $State(w)$, which exactly means that w is a *concrete deadlock state*. This opens up a second possibility for trying to *automatically check* that the deadlock freedom invariant fails for the symbolic initial state $u_1 \vee \dots \vee u_n$ as follows. Assuming that \mathcal{R} satisfies the additional property that $\forall (l \rightarrow r) \in R, vars(l) = vars(r)$, its inverse theory \mathcal{R}^{-1} (see Appendix 2 to Lecture 21) is *executable by rewriting*, we will have proved that the deadlock freedom invariant fails from $u_1 \vee \dots \vee u_n$ if the Maude search commands:

$$\text{search [1] } w \Rightarrow^* u_1$$

$1 \leq i \leq n$ in the system module `mod \mathcal{R}^{-1} endm` finds a solution for this search query.¹ But such a search command may not find a solution, even when \mathcal{R} fails to be deadlock-free from $u_1 \vee \dots \vee u_n$, since although w is a deadlock state, it may not be reachable from any of the ground states specified by $u_1 \vee \dots \vee u_n$. Therefore, either failure to find a solution to the query in finite

¹More generally, we could repeatedly add equations $State(w_i) = true$ to the SCC check to get a sequence of ground deadlock states $w = w_0, w_1, \dots, w_n \dots$ and perform such checks on them, or even use a *generalization algorithm modulo B* [2, 1] to learn pattern terms and check that they represent deadlock states.

time, or infinite looping searching for such a solution do not allow us to settle whether \mathcal{R} is actually deadlock-free from $u_1 \vee \dots \vee u_n$ or not: other methods are needed.

Method 2: Check the Deadlock Freedom Invariant by Narrowing Search

Assuming that the lefthand sides of rules in the topmost rewrite theory $\mathcal{R} = (\Sigma, B, R)$ are left-linear, and that all constructor symbols in such lefthand sides belong to a subsignature $\Sigma_0 \subseteq \Sigma$ of *absolutely free constructors*, i.e., constructors that do not obey any axioms in B , if we fail to prove \mathcal{R} never terminating by the sufficient completeness check described above, we still have another alternative, namely, to specify the *complement* of the set of ground instances of the set of Σ_0 -constructor patterns $\{l_i \mid 1 \leq i \leq k\}$ by another set of Σ_0 -constructor patterns, say $\{v_j \mid 1 \leq j \leq n\}$. Then, \mathcal{R} will be *deadlock free* from a symbolic initial state $u_1 \vee \dots \vee u_m$ iff none of the above patterns v_j can be reached from some u_l , $1 \leq l \leq m$, by narrowing search using the `fvu-narrow` command. The terms $\{v_j \mid 1 \leq j \leq n\}$ can be chosen in two ways:

1. **Automatically**, by using the order-sorted pattern complement algorithm defined in [3].
2. **By hand** (which allows linear patterns that are free modulo B), by actually *guessing* such patterns and then checking two properties automatically:
 - (a) **Generation**: that the set $\{l_i \mid 1 \leq i \leq k\} \cup \{v_j \mid 1 \leq j \leq n\}$ is a *generator set* of sort *State* by the method already described above.
 - (b) **Disjointness**: that for all i, j , $1 \leq i \leq k$ and $1 \leq j \leq n$, the equalities $l_i = v_j$ have no *B-unifiers*.
