Berkeley Ninja Architecture
ACID vs BASE

1. Strong Consistency
2. Availability not considered
3. Conservative

--> Traditional databases

1. Weak consistency
2. Availability is a primary design element
3. Aggressive

--> large-scale distributed systems
CAP Theorem:

Of the three different qualities (network partitions, consistency, availability), at most two of the three qualities can be maintained for any given system.
Forfeit Partitions

- Consistency
- Availability
- Tolerance to network Partitions

Examples:
- Single-site databases
- Cluster databases
- LDAP
- xFS file system

Traits:
- 2-phase commit
- cache validation protocols
Forfeit Availability

Examples
- Distributed databases
- Distributed locking
- Majority protocols

Traits
- Pessimistic locking
- Make minority partitions unavailable

PODC Keynote, July 19, 2000
Forfeit Consistency

- Consistency
- Availability
- Tolerance to network Partitions

Examples
- Coda
- Web caching
- DNS

Traits
- expirations/leases
- conflict resolution
- optimistic
Boundary between entities

1. Remote Procedure Calls
   --> The way it is used currently is not sustainable for larger systems

2. Trusting the other side
   --> need to check arguments before executing RPC

3. Multiplexing between many different clients
   --> How this is done effects boundary definition
Key Messages

1. Parallel programming tends to avoids the notion of availability, online evolution, checkpoint/restart (although currently this is changing)

2. For Robustness in distributed systems, we must think probabilistically about system design qualities

3. Message-Passing seems to be most effective solution, as boundaries must be clearly defined.

4. Need to have more support for partial failure, graceful degradation, and parallel I/O
Discussion

1. Do you believe that techniques applied in distributed database community also can apply to large-scale distributed systems? Or does a completely new approach need to be taken?

2. This work was presented in 2000. Do the principles of robustness apply for today's distributed systems?

3. Do you agree with the notion that without clear boundaries, large-scale distributed systems will remain unmaintainable?
Cumulus: A FileSystem Backup to the Cloud
Back-up to the cloud: Thin or thick?

- **Problem:** Price back-up attractively:
  - Minimize cost of storage
  - Minimize cost of shipping data

- **Solution:**
  - Integrated solutions
  - Back-up specific SW on clients and data centers
  - Thick Cloud

- Portability?
- Provider Monopoly?
Cumulus Design Choice

1. Minimal Interface (4 commands)
2. Highly portable
3. Efficient (through simulation)
4. Practicality (Amazon S3 prototype)
## A Cloud Computing Design Decision

<table>
<thead>
<tr>
<th>Software as a Service (thick cloud)</th>
<th>Utility Computing (thin cloud)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Highly specific implies Better Performance</td>
<td>1. Abstract</td>
</tr>
<tr>
<td>2. Reduced Flexibility</td>
<td>2. Portable</td>
</tr>
<tr>
<td></td>
<td>3. Less Efficient</td>
</tr>
</tbody>
</table>

What is the right choice? And is there a right choice?
Comparison of Cumulus to Other Systems

- Simplest backup system that most will be familiar with: `tar`, `gzip`
- Others: `rsync`, `rdiff-backup`, `Box Backup`, `Jungle Disk`, `Duplicity`, `Brackup`

--> In contrast to all other systems, *Cumulus supports multiple snapshots, simple servers, incremental backups, sub-file disk storage, and encryption.*
Simple User Commands

Get: given a pathname, retrieve the contents of a file from the server

Put: Store the complete file on the server, given its pathname

List: Get the names of files stored on server

Delete: Remove the given file from the server, reclaiming its space

With these four commands, one can support incremental backups on a wide variety of systems.
1. The above illustrates how snapshots are structured on a storage server, using Cumulus.

2. Two different snapshots are taken (on two different days), and each snapshot contains two separate files (labeled file1 and file2).

3. The file1 changes between the two days, while file2 is the same between the two snapshots.

4. The snapshot descriptor contains the date, root, and its corresponding segments.
Cumulus Research Questions

What is the **penalty of using a thin cloud service** with a very simple storage interface compared to a more sophisticated service?

What are the **monetary costs** for using remote backup for two typical usage scenarios? How should remote backup strategies adapt to minimize monetary costs as the ratio of network and storage prices varies?

How does our prototype implementation **compare with other backup systems**? What are the additional benefits (e.g., compression, sub-file incrementals) and overheads (e.g., metadata) of an implementation not captured in simulation? What is the performance of using an online service like Amazon S3 for backup?
Experimental Setup for Simulation

- Two traces are considered as representative workloads for simulation: file-server and user
- For both workloads, traces contain a daily record of meta-data of all files
- Thin service model is compared to optimal backup, where only the needed storage/transfer is done, and no more.
- There are justifiable reasons that Cumulus does not try to store each file in one segment because of the other design goals it aims for (encryption, compression, etc.)
- Statistics are established for both workloads, as shown below.

<table>
<thead>
<tr>
<th></th>
<th>Fileserver</th>
<th>User</th>
</tr>
</thead>
<tbody>
<tr>
<td>Duration (days)</td>
<td>157</td>
<td>223</td>
</tr>
<tr>
<td>Entries</td>
<td>26673083</td>
<td>122007</td>
</tr>
<tr>
<td>Files</td>
<td>24344167</td>
<td>116426</td>
</tr>
<tr>
<td><strong>File Sizes</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Median</td>
<td>0.996 KB</td>
<td>4.4 KB</td>
</tr>
<tr>
<td>Average</td>
<td>153 KB</td>
<td>21.4 KB</td>
</tr>
<tr>
<td>Maximum</td>
<td>54.1 GB</td>
<td>169 MB</td>
</tr>
<tr>
<td>Total</td>
<td>3.47 TB</td>
<td>2.37 GB</td>
</tr>
<tr>
<td><strong>Update Rates</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>New data/day</td>
<td>9.50 GB</td>
<td>10.3 MB</td>
</tr>
<tr>
<td>Changed data/day</td>
<td>805 MB</td>
<td>29.9 MB</td>
</tr>
<tr>
<td>Total data/day</td>
<td>10.3 GB</td>
<td>40.2 MB</td>
</tr>
</tbody>
</table>
Establishing Cleaning Threshold

1. As the cost of storage increases, cleaning more aggressively gives advantage

2. Ideal threshold stabilizes at .5 to .6, when storage is 10 times as expensive as network
Cumulus Experimental Simulation

Figure 3: Overheads for backups in the fileserver trace.

Figure 4: Overheads for backups in the user trace.
Broader Impact

“Can one build a competitive product economy around a cloud of abstract commodity resources, or do underlying technical reasons ultimately favor an integrated service-oriented architecture?”

→ On one hand, if Cumulus is to be accepted as a general solution for file system backup, many more application must be tested and simulated.

→ On the other hand, the need for standardization in the cloud is very important, and a solution like Cumulus should be adopted as quickly as possible.
Discussion Questions for Cumulus

1. Application-specific solutions vs. general light-weight, portable solutions?

2. Who are the users of Cumulus? Would such a backup tool be easy to pick up for a novice?

3. Is the interface provided adequate? Should there be more functionality?

4. Is the issue of security with backing up data adequately addressed?
Smoke and Mirrors: Reflecting Files at a Geographically Remote Location Without Loss of Performance

USENIX 09
Why mirror data?

- Faster Access
- Better Availability
- Data protection against loss (Disaster Tolerance)
Synchronous Mirroring (Remote Sync)

• Reliable
• Slow (Application effectively pauses between step 1 and 6)
Semi-synchronous Mirroring

- Faster
- Less Reliable
Asynchronous Mirroring (Local Sync)

- Faster
- Least Reliable
Mirroring Options:

- Synchronous Mirroring
- Semi-Synchronous Mirroring
- Asynchronous Mirroring

Decreasing Reliability, Decreasing Mirroring Latency
Failure Model

- Can occur at any level
- Simultaneous or in sequence (rolling disaster)
- Network elements can drop packets
## Data Loss Model

<table>
<thead>
<tr>
<th>Failure</th>
<th>Synchronous Mirroring</th>
<th>Semi-Synchronous Mirroring</th>
<th>Asynchronous Mirroring</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary only</td>
<td>No Loss</td>
<td>No Loss</td>
<td>Data Loss</td>
</tr>
<tr>
<td>Primary and Packet Loss on Link</td>
<td>No Loss</td>
<td>Data Loss</td>
<td>Data Loss</td>
</tr>
<tr>
<td>Primary and Mirror</td>
<td>Data Loss</td>
<td>Data Loss</td>
<td>Data Loss</td>
</tr>
</tbody>
</table>
Network Sync Remote Mirroring

- Proactively send error recovery data
- Expose status of data to the application
Network Sync Remote Mirroring

<table>
<thead>
<tr>
<th>Mirror Solution</th>
<th>Mirror Update</th>
<th>Mirror-ack Receive</th>
<th>Mirror-ack Latency</th>
<th>Rolling Disaster</th>
</tr>
</thead>
<tbody>
<tr>
<td>Local-sync</td>
<td>Async- or Semi-sync</td>
<td>N/A</td>
<td>N/A</td>
<td>Loss</td>
</tr>
<tr>
<td>Remote-sync</td>
<td>Synchronous</td>
<td>Storage-level ack (7)</td>
<td>WAN RTT</td>
<td>No loss</td>
</tr>
<tr>
<td>Network-sync</td>
<td>Semi-sync</td>
<td>nw-sync feedback (3)</td>
<td>≈ Local ping</td>
<td>≈ No loss</td>
</tr>
</tbody>
</table>

Table 1: Comparison of Mirroring Protocols.
Smoke and Mirror File System (SMFS)

- A distributed log-structured file system
- Clients interact with file server
- File server interacts with storage servers
- `create()`, `append()`, `free()` operations mirrored

Figure 5: File System Architecture: Applications communicate with the file server through (possibly) a NFS interface. The file server in turn communicates with the metadata server through the `create()` function call. The metadata server allocates space for the newly created log on storage servers that it selects. The file server then interacts directly with the storage server for `append()`, `read()`, and `free()` operations.
Experimental Set-up

- Emulab
- Two clusters of 8 machines each (Primary and Remote)
- Separated by WAN 50-200ms RTT and 1Gbps
- Workload of up to 64 testers
  - Tester is an individual application with only one outstanding request at a time
Evaluation Metrics

- Data Loss
- Latency
- Throughput
Experimental Configurations

- Local-sync
- Remote-sync
- Network-sync
- Local-sync+FEC
- Remote-sync+FEC
Results: Data Loss

- Wide area link failure
- Primary site crash
- Loss rate increased for 0.5 sec before disaster

Figure 6: Data loss as a result of disaster and wide-area link failure, varying link loss (50 ms one-way latency and FEC params \((r, c) = (8, 3)\)).
Results: Varying the level of Redundancy

Figure 7: Data loss as a result of disaster and wide-area link failure, varying FEC param \( c \) (50ms one-way latency, 1% link loss).
Results: Throughput

Figure 9: Effect of varying wide-area one-way link loss on Aggregate Throughput.
Discussion

- Solution is still imperfect
- What if there are multiple remote sites to choose from?
- Split data across different sites?
