

# Epidemic Algorithms for replicated Database maintenance

Alan Demers et al

Xerox Palo Alto Research Center, PODC 87

Presented by: Harshit Dokania

# Motivation

- Replicated Databases

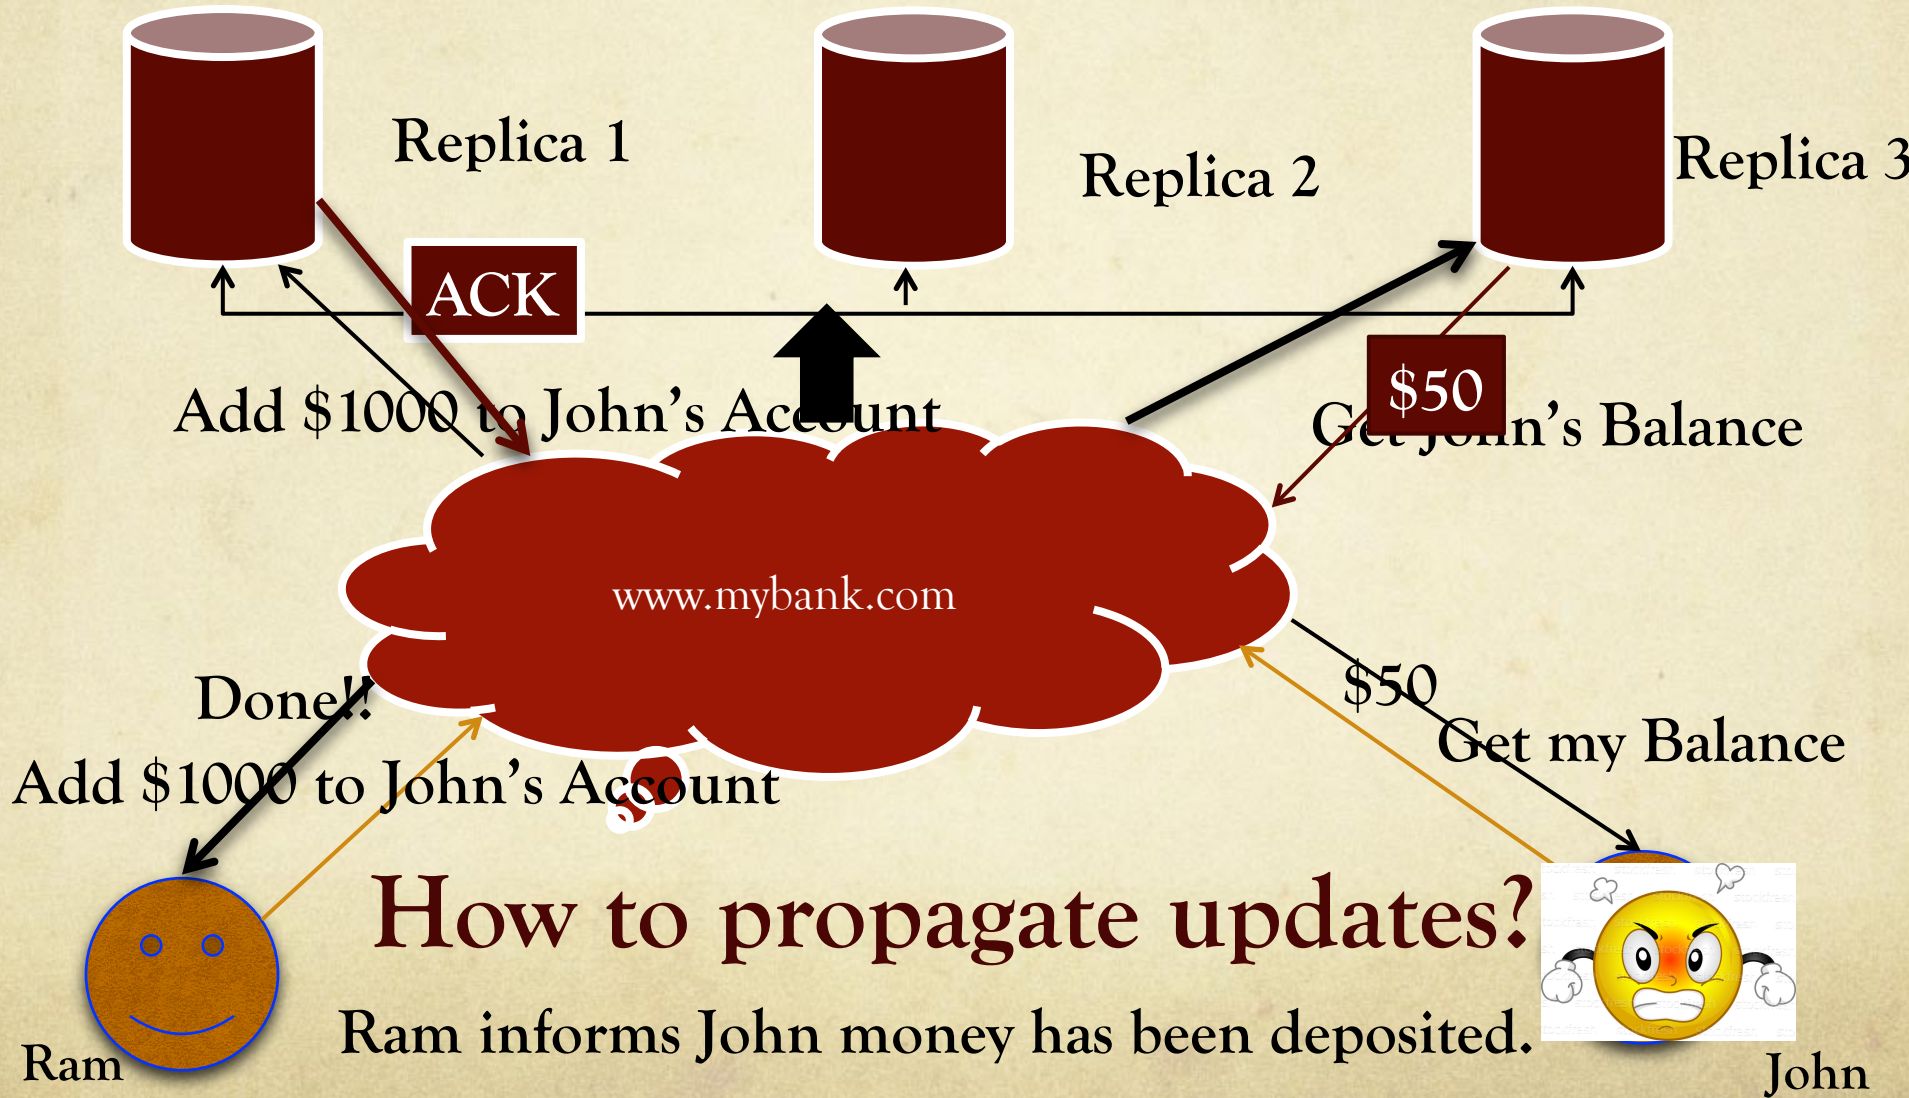

Availability, Fault – tolerant, Faster reads

Consistency

Eventual Consistency : Epidemic Algorithms

Faster reads, writes

# Why Consistency ?

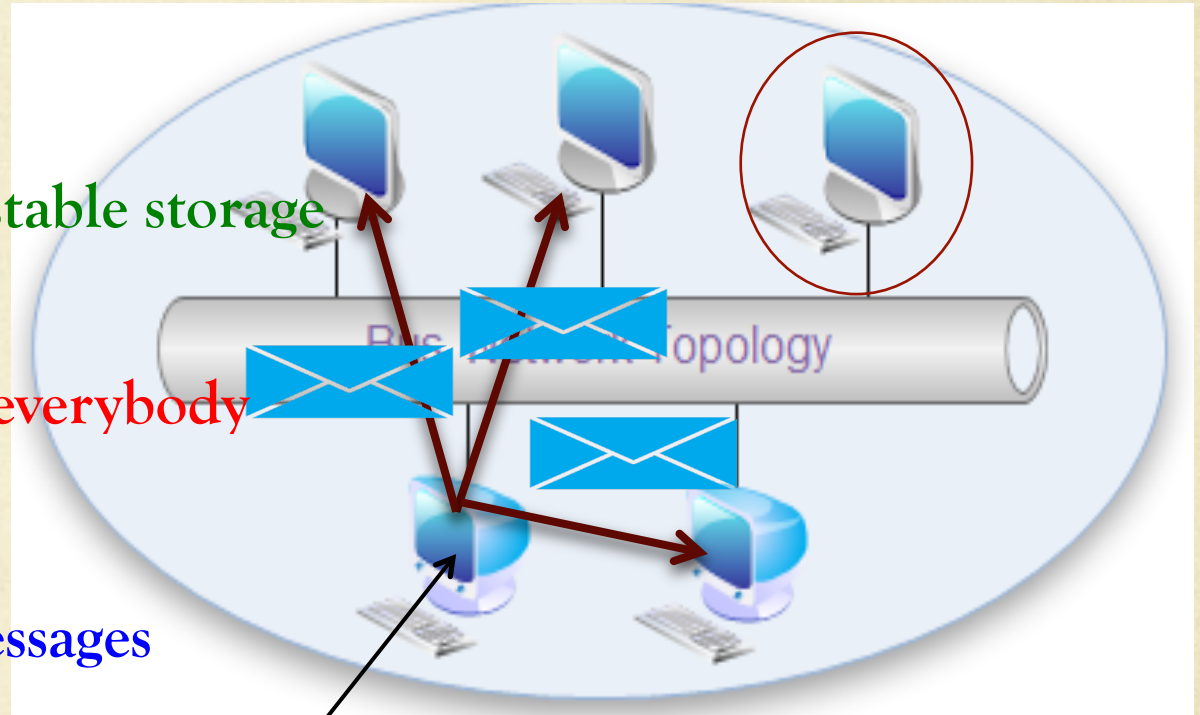

# How to Propagate Updates?

- Direct Mail
- Anti-entropy - Simple Epidemic  
**infected** or **susceptible** sites
- Rumor Mongering - Complex Epidemic  
**infected**, **susceptible** and **removed**

Goal: For all  $s, s' \in S$ :  $s.valueOf = s'.valueOf$

# Direct Mail

- Messages are queued, stable storage  
Reliable but...
- Not everybody knows everybody
- Queue overflows

Source site =  $O(n)$  messages

Traffic = # sites \* Average distance b/w the sites

Anti-Entropy in Background

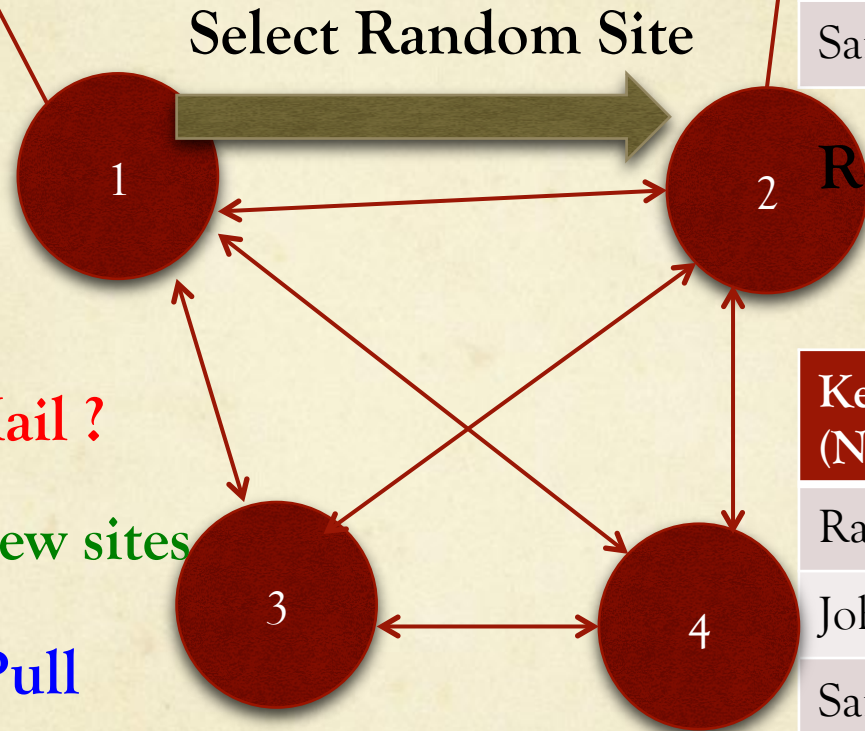

Update[v : V] = s.ValueOf  $\leftarrow$  (v, GMT)

# Anti-Entropy

| Key (Name) | Value (Bal) | Time (GMT) |
|------------|-------------|------------|
| Ram        | 5000        | 110        |
| John       | 1050        | 110        |
| Sam        | 1200        | 100        |

| Key (Name) | Value (Bal) | Time (GMT) |
|------------|-------------|------------|
| Ram        | 6000        | 100        |
| John       | 50          | 100        |
| Sam        | 1500        | 105        |

| Key (Name) | Value (Bal) | Time (GMT) |
|------------|-------------|------------|
| Ram        | 5000        | 110        |
| John       | 1050        | 110        |
| Sam        | 1500        | 105        |

Slower than Direct Mail ?

Distribute update to few sites

Push, Pull, Push - Pull

# Push vs Pull

- Pull

$p_i$  = Probability of a site remaining susceptible after the  $i^{\text{th}}$  cycle

Only if it Selects susceptible site in  $i+1^{\text{st}}$  cycle

$$p_{i+1} = (p_i)^2 \approx 0$$

- Push

Only if **No** infectious site chose to contact susceptible site

$$p_{i+1} = p_i(1-1/n)^{n(1-p_i)} = p_i e^{-1} \approx 0 \text{ (less rapidly)}$$

**But Anti-Entropy is Expensive!!!**

# Anti-Entropy is Expensive

- Usually Databases are in “nearly” complete agreement

Then why send entire Database across network ?

- Exchange Database only if checksum of Database disagree

Time to update to all sites  $>$  Interval between the updates

- Recent update list that contains all new changes for time window  $t'$

$t'$  MUST  $>$  Time required to distribute the update

- Exchange recent update list, then compare checksums

Checksums agree, Less traffic, Less Database comparison

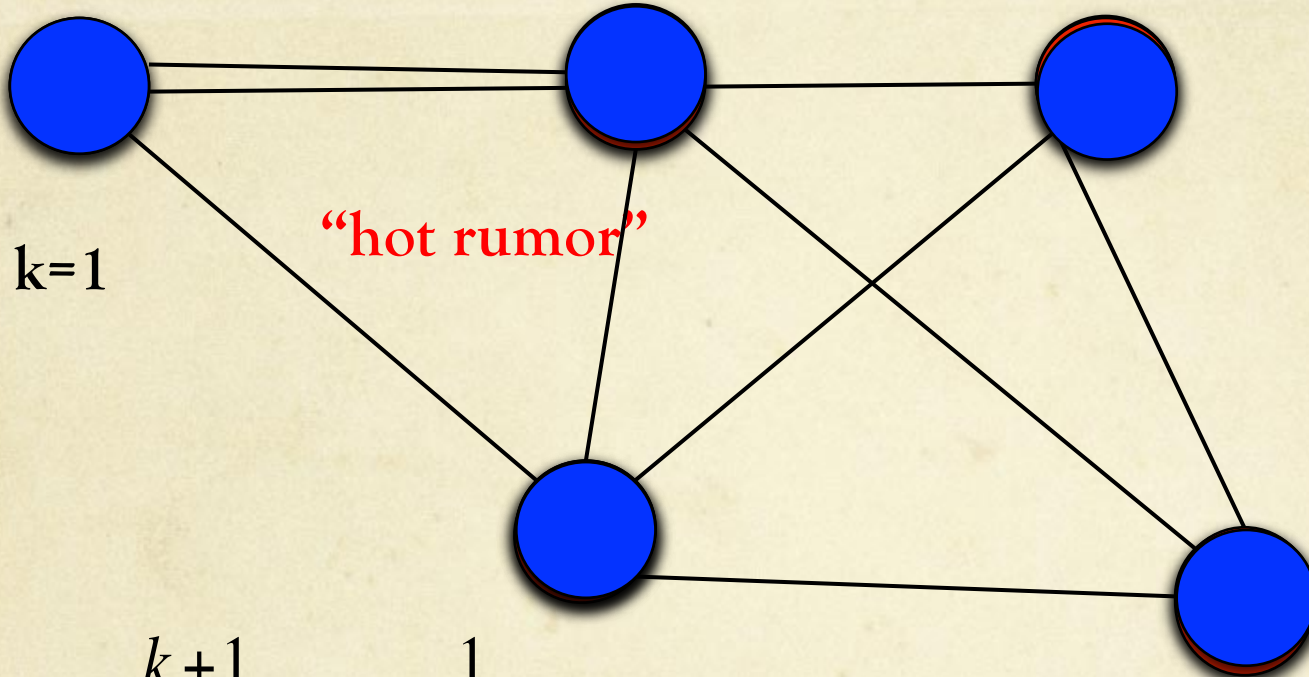

Removed

~~Infected~~

# Rumor Mongering

Susceptible

$$i(s) = \frac{k+1}{k}(1-s) + \frac{1}{k} \log s$$

Convergence,  $i = 0$

$$s = e^{-(k+1)(1-s)}$$

$s = ?$  Residue

# Counter vs Probability

- Become removed after k unnecessary contacts

## Response and Counters

## Blind and Probabilistic

| Counter<br>k | Residue<br>s | Traffic<br>m | Converge<br>$t_{ave}   t_{last}$ |
|--------------|--------------|--------------|----------------------------------|
| 1            | 0.176        | 1.74         | 11.0 16.8                        |
| 2            | 0.037        | 3.30         | 12.1 16.9                        |
| 3            | 0.011        | 4.53         | 12.5 17.4                        |
| 4            | 0.0036       | 5.64         | 12.7 17.5                        |
| 5            | 0.0012       | 6.68         | 12.8 17.7                        |

| Counter<br>k | Residue<br>s | Traffic<br>m | Converge<br>$t_{ave}   t_{last}$ |
|--------------|--------------|--------------|----------------------------------|
| 1            | 0.960        | 0.04         | 19 38                            |
| 2            | 0.205        | 1.59         | 17 33                            |
| 3            | 0.060        | 2.82         | 15 32                            |
| 4            | 0.021        | 3.91         | 14.1 32                          |
| 5            | 0.008        | 4.95         | 13.8 32                          |

Convergence

Push, RM

Traffic

Residue

# Push vs Pull

- Numerous updates

**Susceptible** can find **infective** with high Probability

| Counter<br>k | Residue<br>s    | Traffic<br>m | Convergence |            |
|--------------|-----------------|--------------|-------------|------------|
|              |                 |              | $t_{ave}$   | $t_{last}$ |
| 1            | $3.1 * 10^{-7}$ | 2.70         | 9.97        | 17.63      |
| 2            | $5.8 * 10^{-4}$ | 4.49         | 10.07       | 15.39      |
| 3            | $4.0 * 10^{-6}$ | 6.09         | 10.08       | 14.00      |

Pull, Response and Counters

Exchange counters If both know the update Increment the site with smaller counter

Push gets better than Pull with connection limit. How?

Two sites contact the same recipient One gets rejected Still gets the update

Two sites contact the same infected site One gets rejected Only 1 site updated

# Direct Mail vs Rumor

- Both has no guarantee
  - Anti-entropy is the key
- But what if Anti- entropy finds conflicts ?
  - Let it be...
  - Clearinghouse uses Direct Mail for redistribution

Worst case : DM Manages to deliver an update half the sites

Later AE-DM generates  $O(n^2)$  messages

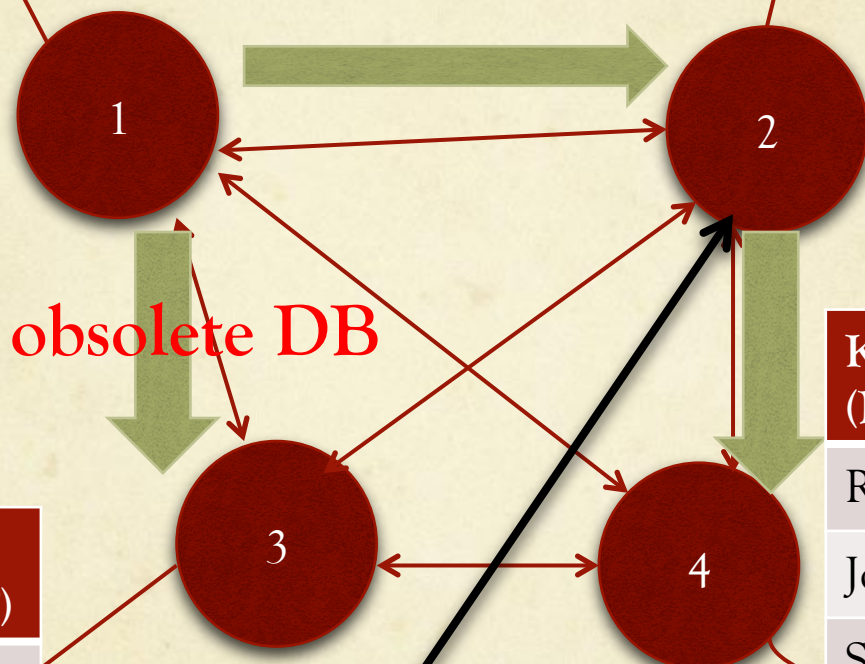

or

AE-RM generates  $O(n)$  messages

# How do we delete?

| Key (Name) | Value (Bal) | Time (GMT) |
|------------|-------------|------------|

Delete  
John, 120

But when do we delete Death Certificates

Looks Easy !!!

| Key (Name) | Value (Bal) | Time (GMT) |
|------------|-------------|------------|
| Ram        | 5000        | 110        |
| Sam        | 1200        | 100        |

Delete my account

John

# Delete Death Certificates

- Delete them after 30 days

Still has risk of **resurrection**

- Sarin and Lynch propose Chandy-Lamport snapshot algorithm

Records **Application** messages when sees **duplicate Marker** messages

**Snapshot** ensures Death certificate received at all sites

But what when site **permanently fails?**

# Dormant Death Certificates

- Delete death certificates at most sites
  - But retain **Dormant** death certificates at some **retention** sites “**r**”
- Obsolete update encounters Dormant certificate
  - Activate** Death certificate
  - Original** timestamp, **Activation** timestamp
- Much larger threshold for Dormant Death Certificates
- But lost due to permanent server **failures**

$$p_{\text{fail}} = 2^{-r}$$

# Spatial Distribution

- Saves significant amount of traffic
- probability of connecting site at distance  $d = d^{-a}$   
when  $a = 2$  ; **convergence** is polynomial in **log n**  
Generalized for CIN with distribution  $d^{-2D}$   
**dependent on dimension of mesh 'D'**
- $Q_s(d) =$  sites at distance  $d$  or less from  $s$   
**arbitrary network** **Best Scaling**

# Using Spatial Distribution

- Anti-Entropy

Uniform distribution  $\approx 80$  conversations on **critical links**

Expected traffic **per link per cycle**  $< 6$  conversations

$Q_s(d)$  adapts well to “**local dimension**”

- Rumor Mongering

Making it less sensitive for sudden increases in  $Q_s(d)$

Each site  $s$  builds a list of sites sorted by distance

For  $a = 2$  again complexity is  $O(d^{2d})$

# Simulation Results: AE

Push-Pull, No Connection limit

Push-Pull, Connection limit 1

Feedback, Counter, Push-Pull, No connection limit

With increase in “a”, k increases gradually Convergence time **increases**

**Decrease** in Average traffic  $\approx$  factor of 3

**Massive decrease** in compare traffic for transatlantic links  $>$  factor of 30

# Discussion

- Anti- Entropy is **robust** than Rumor Mongering

Rumors may become **inactive** leaving sites **susceptible**

- Push  $\xi$  Pull much sensitive to spatial distribution than Push-Pull (RM)

k = **36** for a = 1.2 (Push, Feedback, No connection limit, Counter)

- Anti - Entropy with distribution of  $d^2$  was implemented at CIN

Massive **improvement** in network load  $\xi$  consistency

# Cons/Questions

- **Storage**, Death Certificates
- **Irregular** Network Topologies
  - **Dynamic Hierarchy**
