Clustering with Application to Fast Object Search

Computer Vision
CS 543 / ECE 549
University of Illinois

Derek Hoiem

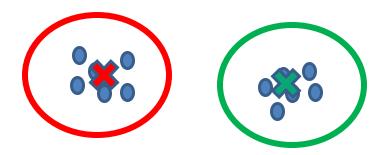

This section

- Clustering: grouping together similar points, images, feature vectors, etc.
- Segmentation: dividing the image into meaningful regions
 - Segmentation by clustering: K-means and mean-shift
 - Graph approaches to segmentation: graph cuts and normalized cuts
 - Segmentation from boundaries: watershed
- EM: soft clustering, or parameter estimation with hidden data

Today's class

- Clustering algorithms
 - K-means
 - Application to fast object search
 - Hierarchical clustering
 - Spectral clustering

Clustering: group together similar points and represent them with a single token

Key Challenges:

- 1) What makes two points/images/patches similar?
- 2) How do we compute an overall grouping from pairwise similarities?

Why do we cluster?

Summarizing data

- Look at large amounts of data
- Patch-based compression or denoising
- Represent a large continuous vector with the cluster number

Counting

Histograms of texture, color, SIFT vectors

Segmentation

Separate the image into different regions

Prediction

Images in the same cluster may have the same labels

How do we cluster?

- K-means
 - Iteratively re-assign points to the nearest cluster center
- Agglomerative clustering
 - Start with each point as its own cluster and iteratively merge the closest clusters
- Spectral clustering
 - Split the nodes in a graph based on assigned links with similarity weights

Clustering for Summarization

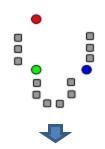

Goal: cluster to minimize variance in data given clusters

Preserve information

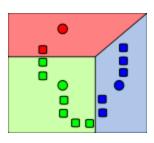

$$\mathbf{c}^*, \boldsymbol{\delta}^* = \underset{\mathbf{c}, \boldsymbol{\delta}}{\operatorname{argmin}} \frac{1}{N} \sum_{j}^{N} \sum_{i}^{K} \mathcal{S}_{ij} (\mathbf{c}_{i}^{j} - \mathbf{x}_{j}^{j})^2$$
Whether \mathbf{x}_{i} is assigned to \mathbf{c}_{i}

K-means algorithm

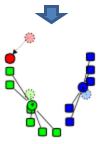

1. Randomly select K centers

2. Assign each point to nearest center

3. Compute new center (mean) for each cluster

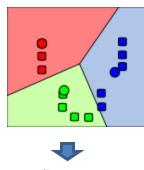

K-means algorithm

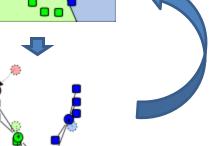

1. Randomly select K centers

2. Assign each point to nearest center

3. Compute new center (mean) for each cluster

Back to 2

Illustration: http://en.wikipedia.org/wiki/K-means_clustering

K-means

- 1. Initialize cluster centers: \mathbf{c}^0 ; t=0
- 2. Assign each point to the closest center

$$\boldsymbol{\delta}^{t} = \underset{\boldsymbol{\delta}}{\operatorname{argmin}} \frac{1}{N} \sum_{i}^{N} \sum_{i}^{K} \delta_{ij} \left(\mathbf{c}_{i}^{t-1} - \mathbf{x}_{j} \right)^{2}$$

3. Update cluster centers as the mean of the points

$$\mathbf{c}^{t} = \underset{\mathbf{c}}{\operatorname{argmin}} \frac{1}{N} \sum_{i}^{N} \sum_{j}^{K} \delta_{ij}^{t} \left(\mathbf{c}_{i} - \mathbf{x}_{j}\right)^{2}$$

4. Repeat 2-3 until no points are re-assigned (t=t+1)

K-means demos

General

http://home.dei.polimi.it/matteucc/Clustering/tutorial html/AppletKM.html

(note: I can't run this anymore because of security settings ☺)

http://util.io/k-means

(works mostly but not great)

Color clustering

http://www.cs.washington.edu/research/imagedatabase/demo/kmcluster/

(note: I can't run this anymore because of security settings ☺)

Kmeans: Matlab code

```
function C = kmeans(X, K)
% Initialize cluster centers to be randomly sampled points
[N, d] = size(X);
rp = randperm(N);
C = X(rp(1:K), :);
bestAssignment = zeros(N, 1);
while true
  lastAssignment = bestAssignment;
  % Assign each point to nearest cluster center
  mindist = Inf*ones(N, 1);
  for k = 1:K
    for n = 1:N
      dist = sum((X(n, :)-C(k, :)).^2);
      if dist < mindist(n)</pre>
        mindist(n) = dist;
        bestAssignment(n) = k;
      end
    end
  end
  % break if assignment is unchanged
  if all(bestAssignment==lastAssignment), break; end;
  % Assign each cluster center to mean of points within it
  for k = 1 \cdot K
    C(k, :) = mean(X(bestAssignment==k, :));
  end
end
```

K-means: design choices

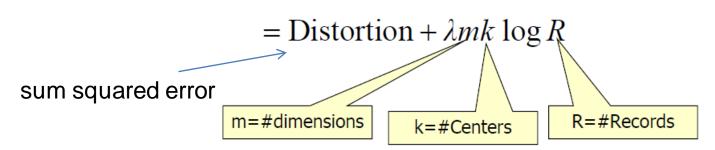

- Initialization
 - Randomly select K points as initial cluster center
 - Or greedily choose K points to minimize residual
- Distance measures
 - Traditionally Euclidean, could be others
- Optimization
 - Will converge to a local minimum
 - May want to perform multiple restarts

How to choose the number of clusters?

Minimum Description Length (MDL) principal for model comparison

- Minimize Schwarz Criterion
 - also called Bayes Information Criteria (BIC)

Distortion + λ (#parameters) log R

How to choose the number of clusters?

- Validation set
 - Try different numbers of clusters and look at performance
 - When building dictionaries (discussed later), more clusters typically work better

How to evaluate clusters?

Generative

— How well are points reconstructed from the clusters?

Discriminative

- How well do the clusters correspond to labels?
 - Purity
- Note: unsupervised clustering does not aim to be discriminative

Common similarity/distance measures

- P-norms
 - City Block (L1)
 - Euclidean (L2)
 - L-infinity

$$\|\mathbf{x}\|_{p} := \left(\sum_{i=1}^{n} |x_{i}|^{p}\right)^{1/p}$$

$$\|\mathbf{x}\|_{1} := \sum_{i=1}^{n} |x_{i}|$$

$$\|\mathbf{x}\| := \sqrt{x_{1}^{2} + \dots + x_{n}^{2}}$$

$$\|\mathbf{x}\|_{\infty} := \max(|x_{1}|, \dots, |x_{n}|)$$

Here x_i is the distance between corresponding elements of vectors

- Mahalanobis
 - Scaled Euclidean

$$d(\vec{x}, \vec{y}) = \sqrt{\sum_{i=1}^{N} \frac{(x_i - y_i)^2}{\sigma_i^2}}$$

Cosine distance

similarity =
$$cos(\theta) = \frac{A \cdot B}{\|A\| \|B\|}$$

Conclusions: K-means

Good

- Finds cluster centers that minimize conditional variance (good representation of data)
- Simple to implement, widespread application

Bad

- Prone to local minima
- Need to choose K
- All clusters have the same parameters (e.g., distance measure is non-adaptive)
- Can be slow: each iteration is O(KNd) for N d-dimensional points

K-medoids

- Just like K-means except
 - Represent the cluster with one of its members,
 rather than the mean of its members
 - Choose the member (data point) that minimizes cluster dissimilarity

- Applicable when a mean is not meaningful
 - E.g., clustering values of hue or using L-infinity similarity

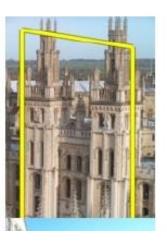

Application of Clustering

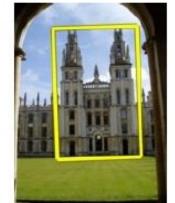

How to quickly find images in a large database that match a given image region?

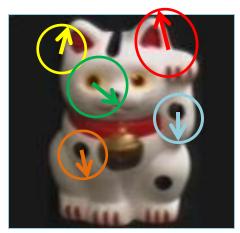

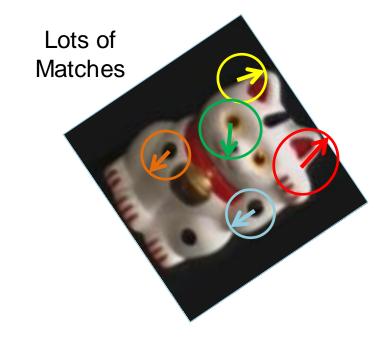

Simple idea

See how many SIFT keypoints are close to SIFT keypoints in each other image

Few or No Matches

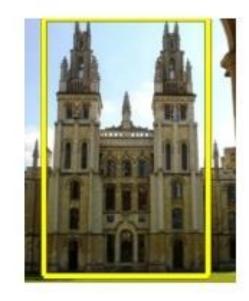

But this will be really, really slow!

Key idea 1: "Visual Words"

- Cluster the keypoint descriptors
- Assign each descriptor to a cluster number
 - What does this buy us?
 - Each descriptor was 128 dimensional floating point, now is 1 integer (easy to match!)
 - Is there a catch?
 - Need a lot of clusters (e.g., 1 million) if we want points in the same cluster to be very similar
 - Points that really are similar might end up in different clusters

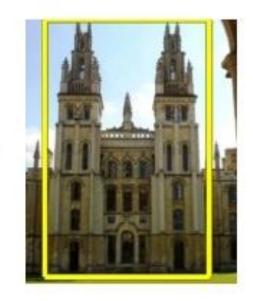

Key idea 1: "Visual Words"

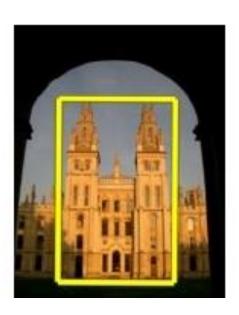

- Cluster the keypoint descriptors
- Assign each descriptor to a cluster number
- Represent an image region with a count of these "visual words"

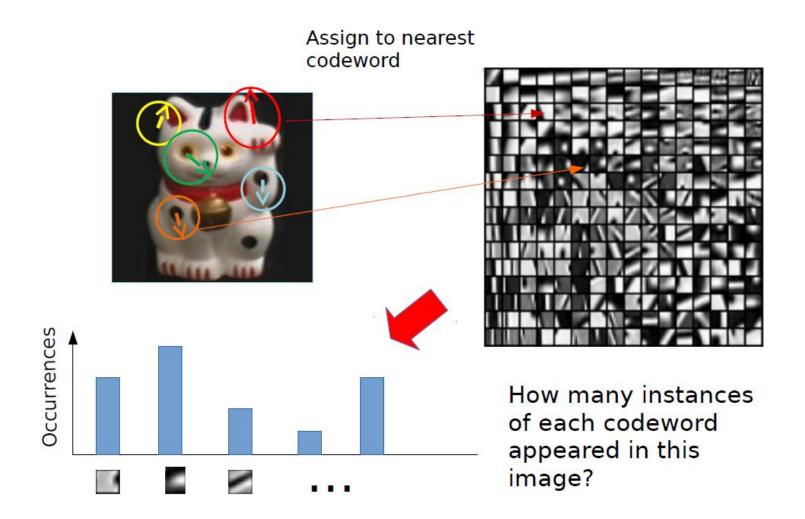

Key idea 1: "Visual Words"

- Cluster the keypoint descriptors
- Assign each descriptor to a cluster number
- Represent an image region with a count of these "visual words"
- An image is a good match if it has a lot of the same visual words as the query region

Naïve matching is still too slow

• Imagine matching 1,000,000 images, each with 1,000 keypoints

Key Idea 2: Inverse document file

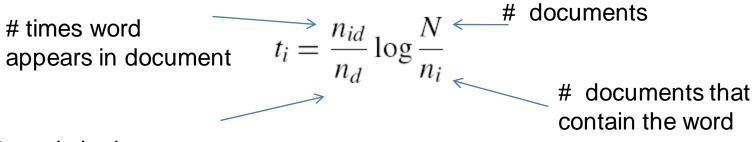

- Inverted Index
 - Analogous to index section of a book
 - Store mapping from codeword to images it appears in
- Fast inner product computation on large datasets:
 - Only operate on images containing relevant codewords

Key Idea 2: Inverse document file

Rank database images based on tf-idf measure.

tf-idf: Term Frequency – Inverse Document Frequency

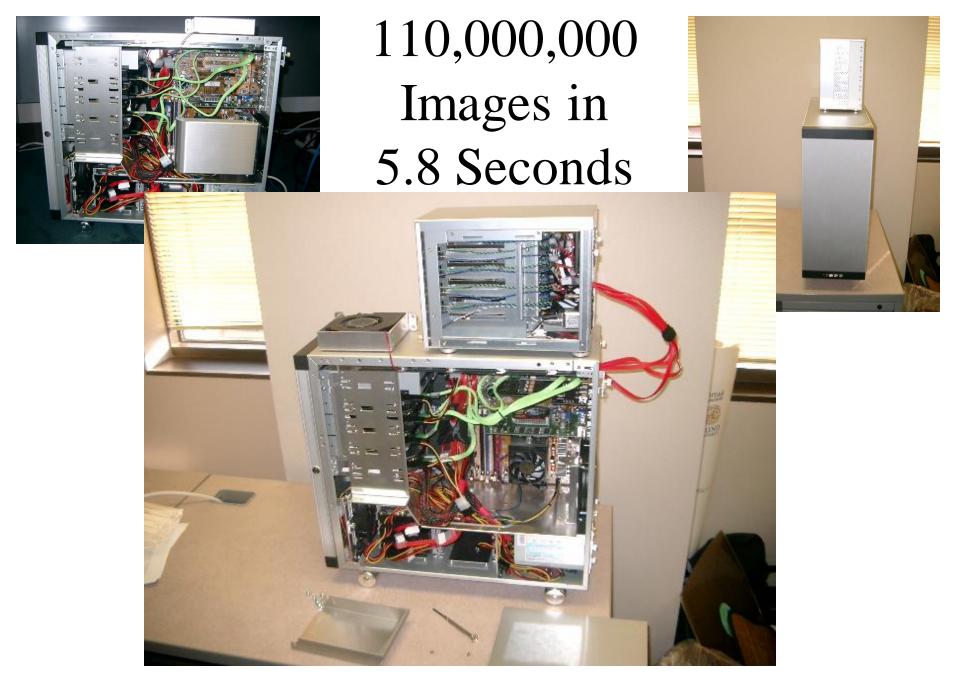

words in document

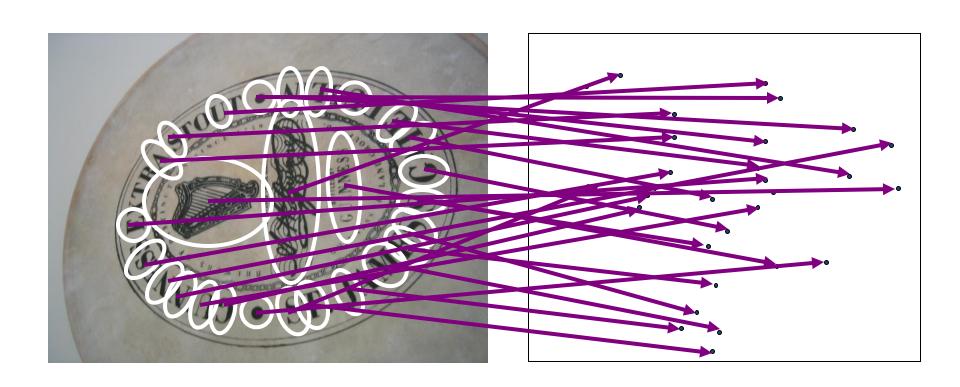

Fast visual search

This slide and following by David Nister

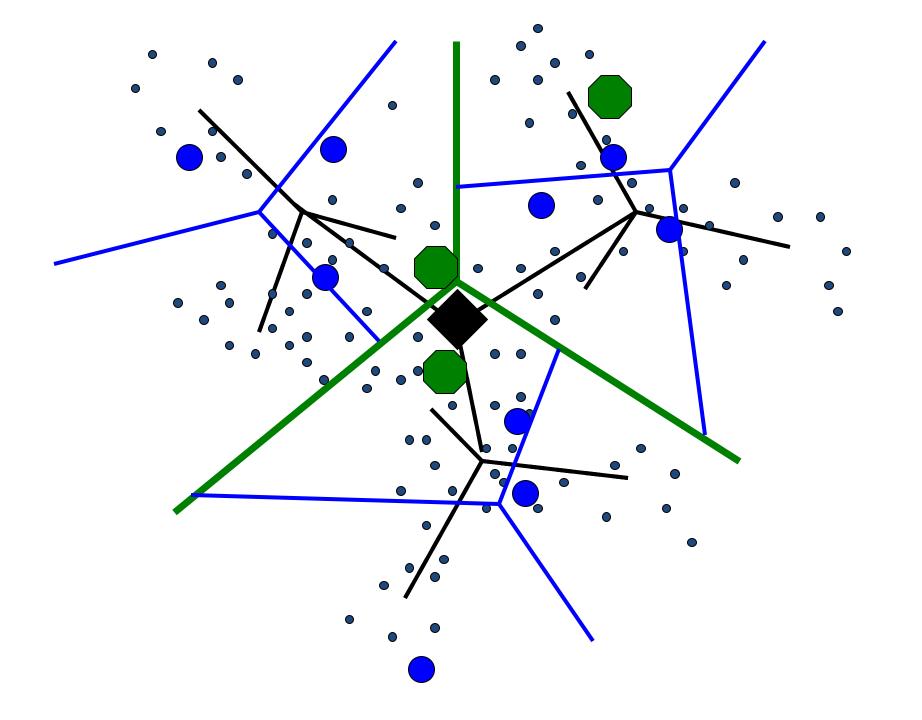

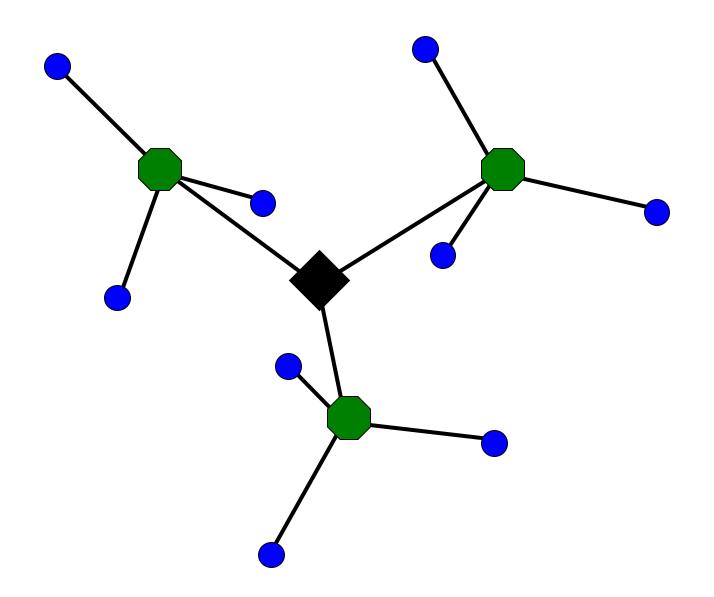

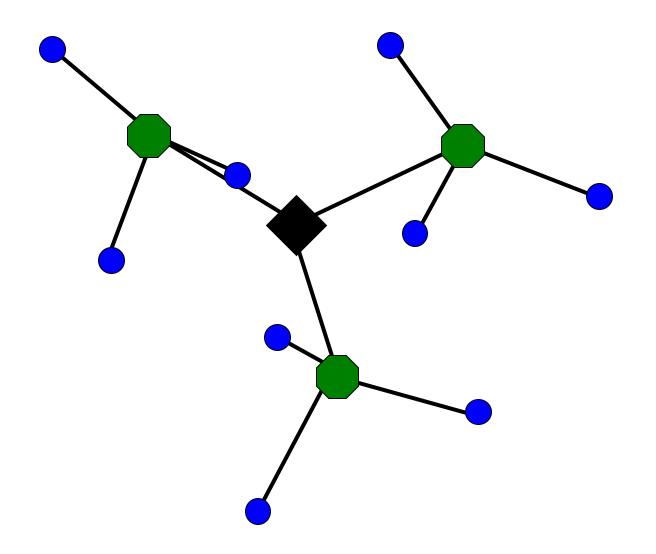

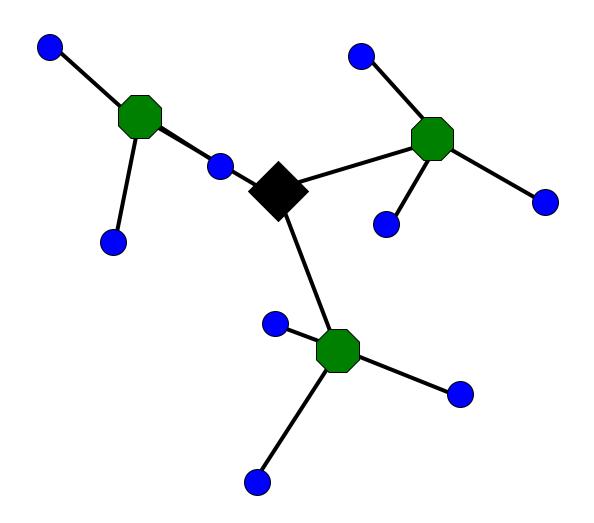

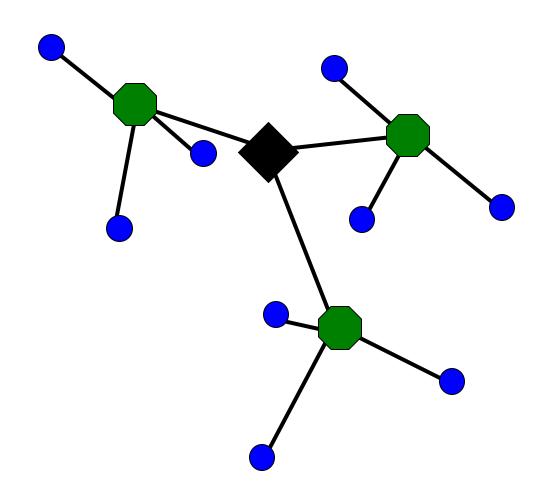

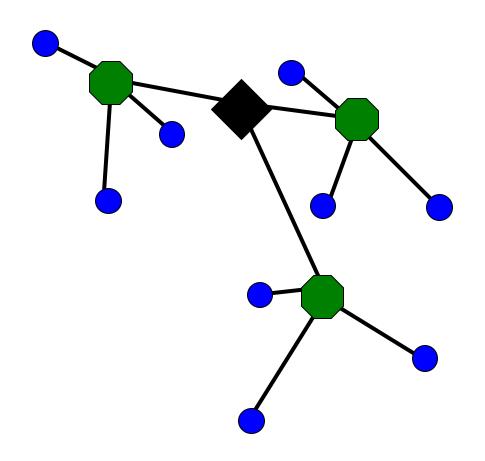

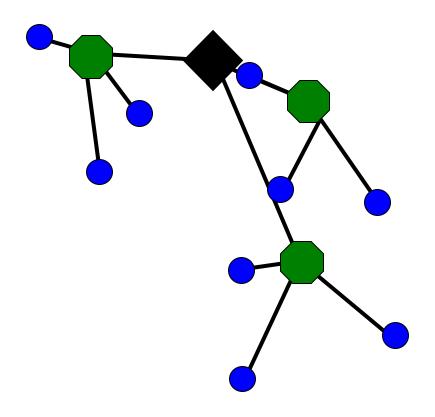

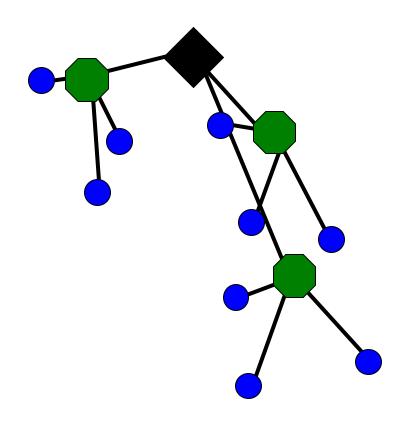

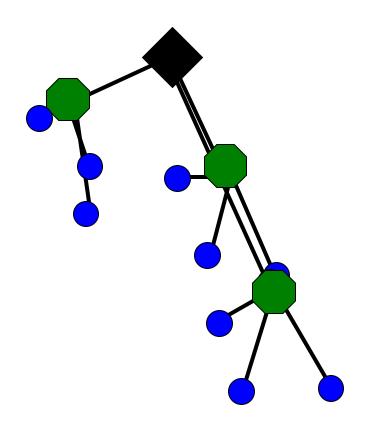

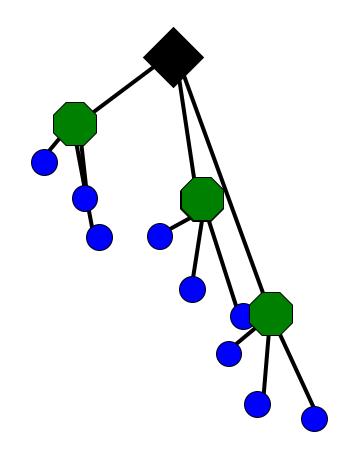

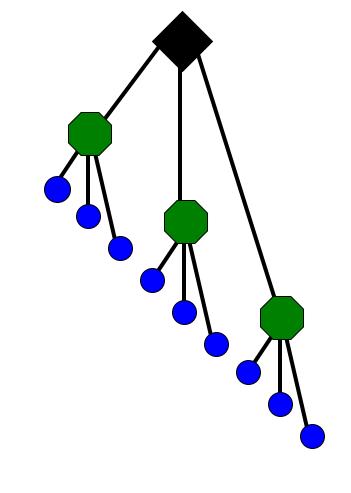

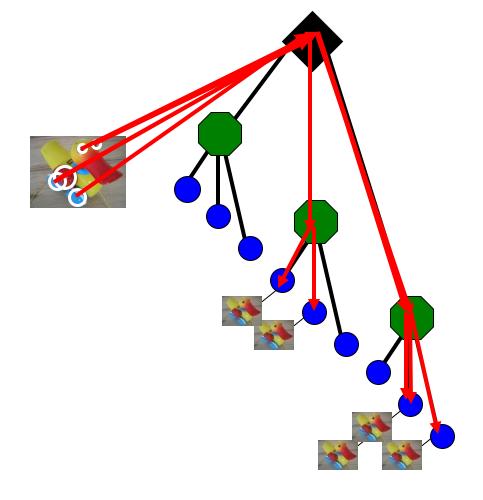

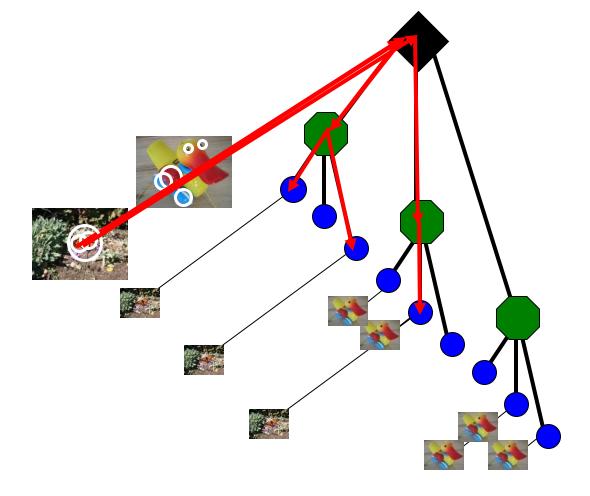

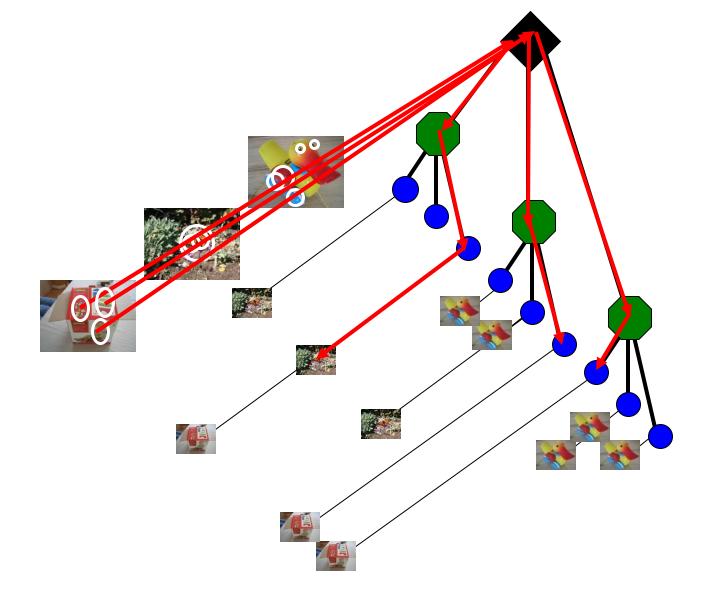

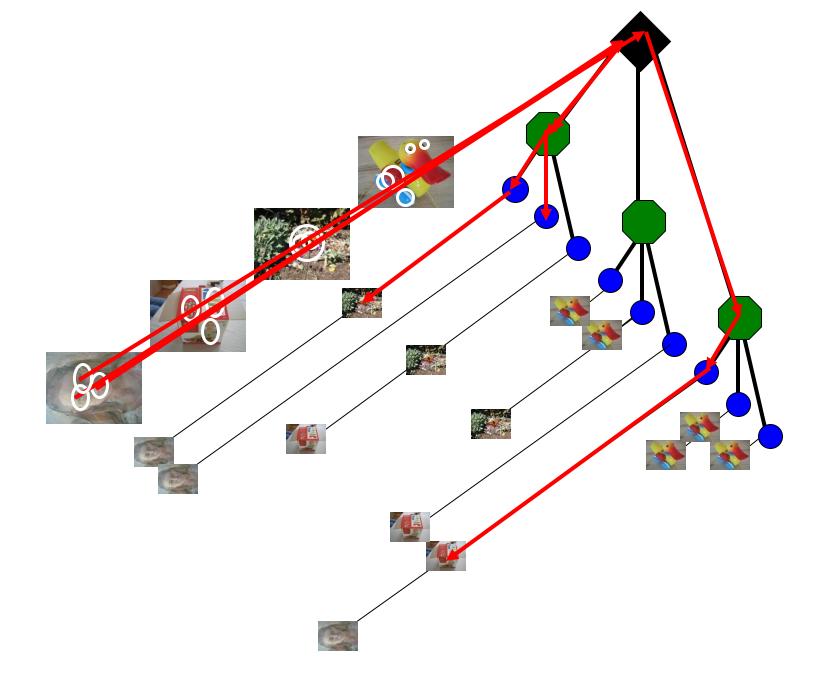

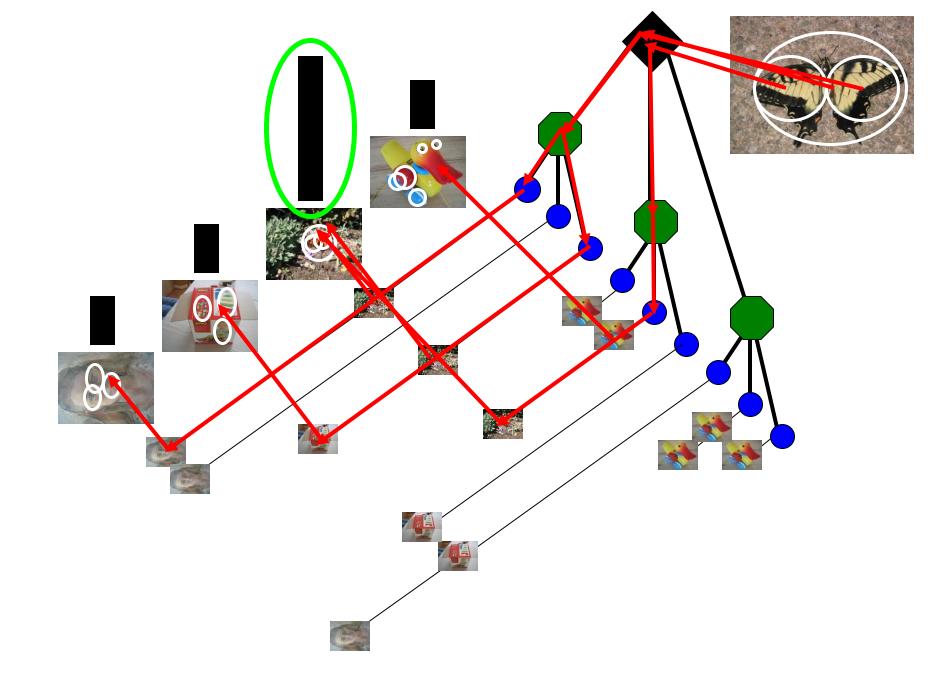

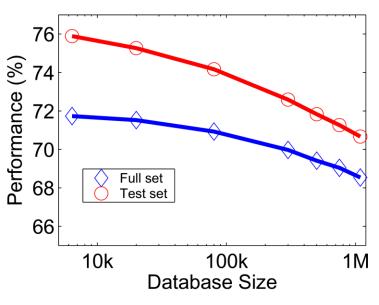

Performance

ImageSearch at the VizCentre

New query: Browse... Send File
File is 500x320

Top n results of your query.

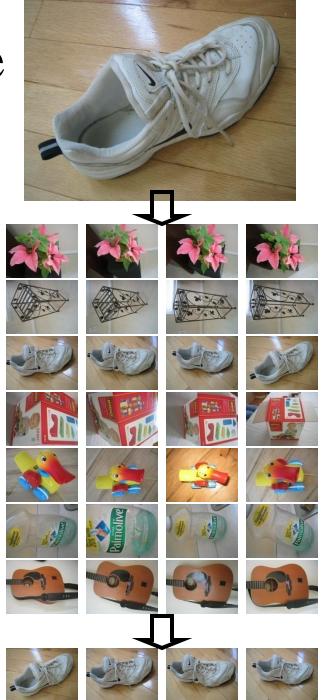

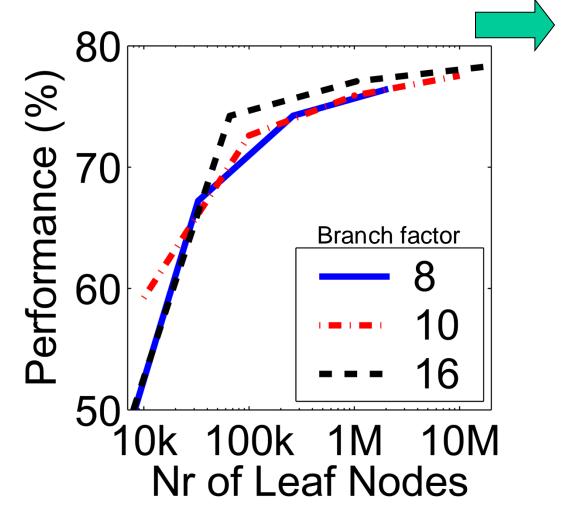

More words is better

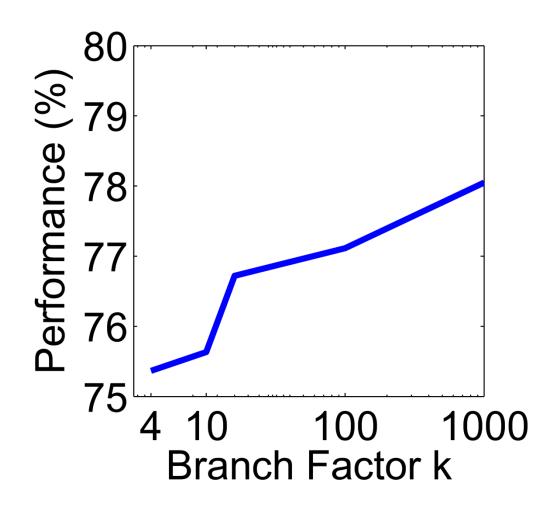

Improves Speed

Higher branch factor works better (but slower)

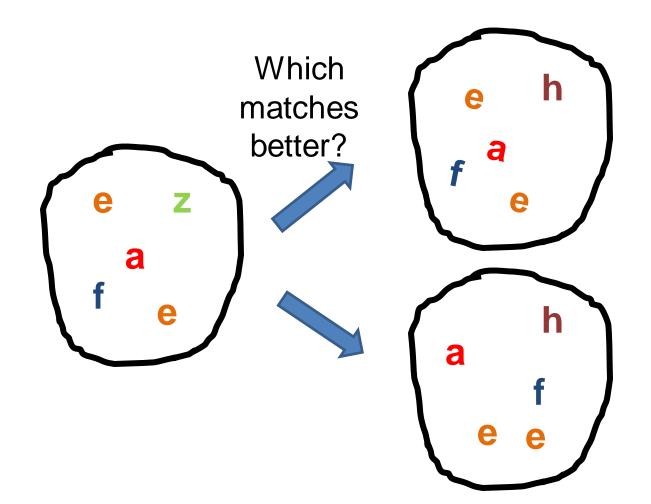

Application: Google Goggles

http://www.google.com/mobile/goggles/#text

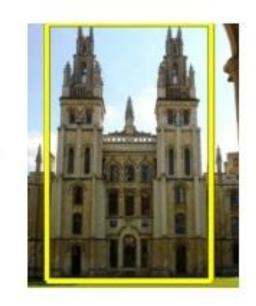

Can we be more accurate?

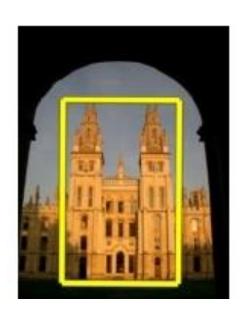

So far, we treat each image as containing a "bag of words", with no spatial information

Can we be more accurate?

So far, we treat each image as containing a "bag of words", with no spatial information

Real objects have consistent geometry

Final key idea: geometric verification

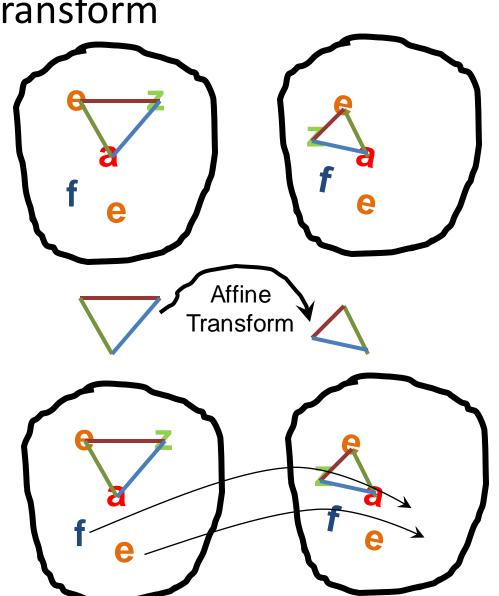

RANSAC for affine transform

Repeat N times:

Randomly choose 3 matching pairs

Estimate transformation

Predict remaining points and count "inliers"

Video Google System

- 1. Collect all words within query region
- 2. Inverted file index to find relevant frames
- 3. Compare word counts
- 4. Spatial verification

Sivic & Zisserman, ICCV 2003

Demo online at:
 http://www.robots.ox.ac.uk/~vgg/research/vgoogle/index.html

Query region

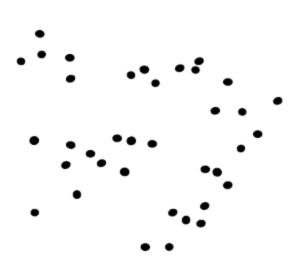

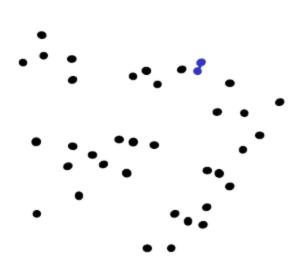

Retrieved frames

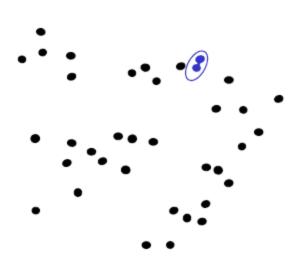

1. Say "Every point is its own cluster"

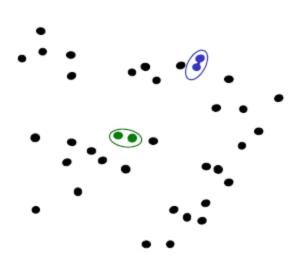

- 1. Say "Every point is its own cluster"
- Find "most similar" pair of clusters

- 1. Say "Every point is its own cluster"
- Find "most similar" pair of clusters
- 3. Merge it into a parent cluster

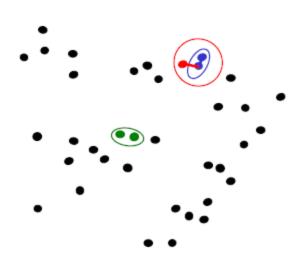

- 1. Say "Every point is its own cluster"
- Find "most similar" pair of clusters
- Merge it into a parent cluster
- 4. Repeat

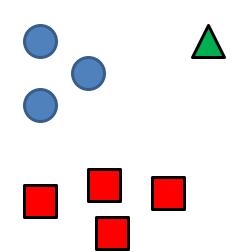

- 1. Say "Every point is its own cluster"
- Find "most similar" pair of clusters
- Merge it into a parent cluster
- 4. Repeat

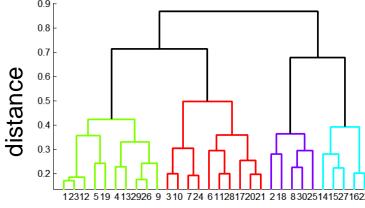

How to define cluster similarity?

- Average distance between points, maximum distance, minimum distance
- Distance between means or medoids

How many clusters?

- Clustering creates a dendrogram (a tree)
- Threshold based on max number of clusters or based on distance between merges

Conclusions: Agglomerative Clustering

Good

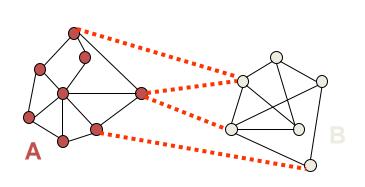

- Simple to implement, widespread application
- Clusters have adaptive shapes
- Provides a hierarchy of clusters

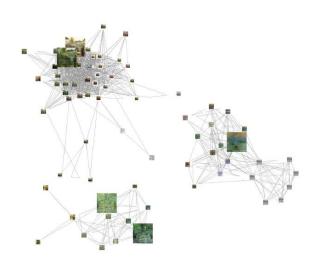

Bad

- May have imbalanced clusters
- Still have to choose number of clusters or threshold
- Need to use an "ultrametric" to get a meaningful hierarchy

Spectral clustering

Group points based on links in a graph

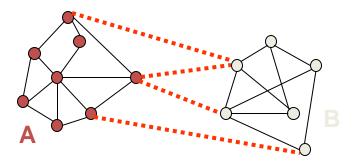

Spectral Clustering

```
function[memb] = spectral cluster(data, c, num clusters)
% a simple implementation for unnormalized spectral clustering
% each row of data should be a data point
%% setup affinity matrix W
num data = size(data,1);
D = zeros(num data, num data);
for i = 1:size(data,1)
  dists = data - repmat(data(i,:), [num data, 1]);
  D(:,i) = sqrt(sum(dists.*dists, 2));
end
W = \exp(-(D.*D)/c);
W = W-diag(diag(W)); % remove diagonal
%% setup degree matrix G
gs = sum(W, 2);
G = diag(gs);
%% compute laplacian
L = G - W:
[V, D] = eigs(L, num clusters, 'sm');
memb = kmeans(V, num clusters);
end
```

Cuts in a graph

Normalized Cut

- the raw cut cost encouraging splitting out just one node
- fix by normalizing for size of segments

$$Ncut(A, B) = \frac{cut(A, B)}{volume(A)} + \frac{cut(A, B)}{volume(B)}$$

volume(A) = sum of costs of all edges that touch A

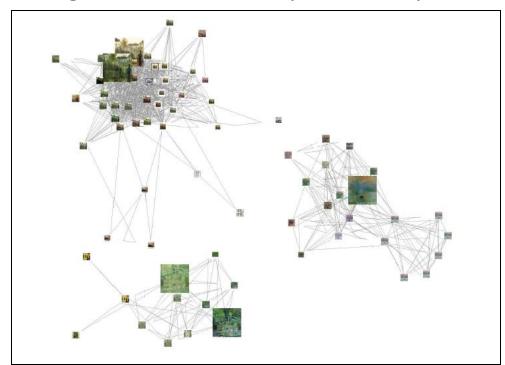

Source: Seitz

Normalized cuts for segmentation

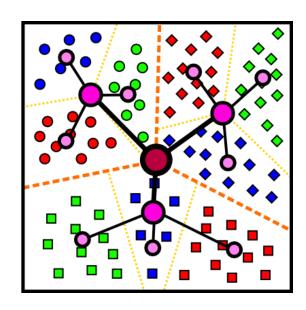

Visual PageRank

- Determining importance by random walk
 - What's the probability that you will randomly walk to a given node?
 - Create adjacency matrix based on visual similarity
 - Edge weights determine probability of transition
 - Rank image search results by stationary distribution

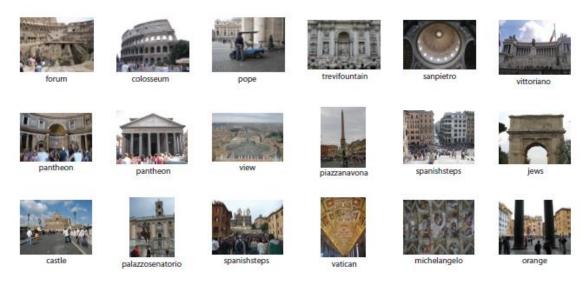

Which algorithm to use?

- Quantization/Summarization: K-means
 - Aims to preserve variance of original data
 - Can easily assign new point to a cluster

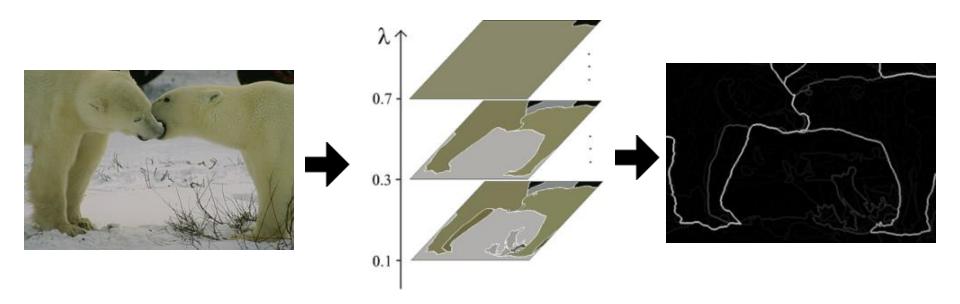

Quantization for computing histograms

Summary of 20,000 photos of Rome using "greedy k-means" http://grail.cs.washington.edu/projects/canonview/

Which algorithm to use?

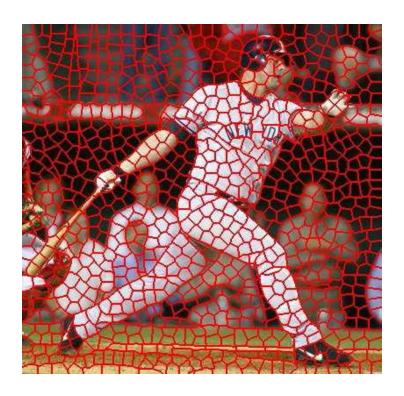

- Image segmentation: agglomerative clustering
 - More flexible with distance measures (e.g., can be based on boundary prediction)
 - Adapts better to specific data
 - Hierarchy can be useful

http://www.cs.berkeley.edu/~arbelaez/UCM.html

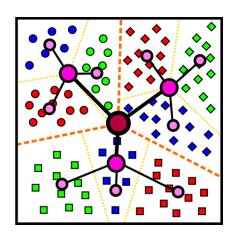

Which algorithm to use?

- Image segmentation: spectral clustering
 - Can provide more regular regions
 - Spectral methods also used to propagate global cues (e.g., Global pB)

Things to remember

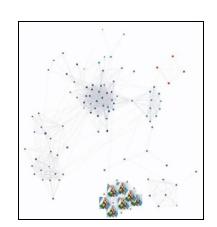

- K-means useful for summarization, building dictionaries of patches, general clustering
 - Fast object retrieval using visual words and inverse index table

 Agglomerative clustering useful for segmentation, general clustering

 Spectral clustering useful for determining relevance, summarization, segmentation
