# CS 573: Algorithms, Fall 2014

# **Approximation Algorithms**

Lecture 8 September 19, 2014 Part I

Max Exact 3SAT

1/69

3SAT revisited

- 1. Instance of **3SAT** is a boolean formula.
- 2. Example:  $F = (x_1 + x_2 + x_3)(x_4 + \overline{x_1} + x_2)$ .
- 3. Decision problem = is the formula has a satisfiable assignment.
- 4. Optimization version:

Max 3SAT

**Instance**: A collection of clauses:  $C_1, ..., C_m$ . Question: Find the assignment to  $x_1, ..., x_n$  that satisfies the maximum number of clauses.

- 5. Max 3SAT is NP-Hard
- 6. Max 3SAT is a maximization problem.

### Some definitions

#### **Definition**

Algorithm Alg for a maximization problem achieves an approximation factor  $\alpha \leq 1$  if for all inputs, we have:

$$rac{\mathsf{Alg}(\mathit{G})}{\mathrm{Opt}(\mathit{G})} \geq lpha.$$

*randomized algorithm*: it is allowed to consult with a source of random numbers in making decisions.

Definition (Linearity of expectations.)

Given two random variables X, Y (not necessarily independent, we have that  $\mathbf{E} [X + Y] = \mathbf{E} [X] + \mathbf{E} [Y]$ .

2/6

# Approximating Max3SAT

#### Theorem

Expected (7/8)-approximation to  $Max\ 3SAT$  in polynomial time.

**F** has m clauses  $\implies$  generated assignment satisfies (7/8)m clauses in expectation.

#### Proof

- 1.  $x_1, \ldots, x_n$ : n variables used.
- 2. Randomly and independently assign 0/1 values to  $x_1, \ldots, x_n$ .
- 3.  $Y_i$ : indicator variable is  $1 \iff i$ th clause in instance is satisfied.
- 4.  $Y = \sum_{i=1}^{m} Y_i$ : # clauses satisfied.

5/69

# Approximating Max3SAT

Concluding remarks

- 1. Algorithm quality independent of opt...
- 2. Algorithm is oblivious.
- 3. ? proved that one can do no better; that is, for any constant  $\varepsilon > 0$ , one can not approximate 3SAT in polynomial time (unless P = NP) to within a factor of  $7/8 + \varepsilon$ .
- 4. Amazing that a trivial algorithm like the above is essentially optimal!

# Approximating Max3SAT - proof continued

#### Proof continued:

1. Claim:  $\mathbf{E}[Y] = (7/8)m$ , m = number of clauses.

$$\mathsf{E}\!\left[\mathsf{Y}\right] = \mathsf{E}\!\left[\sum_{i=1}^{m} \mathsf{Y}_{i}\right] = \sum_{i=1}^{m} \mathsf{E}\!\left[\mathsf{Y}_{i}\right]$$

by linearity of expectation.

2. 
$$\Pr[Y_i = 0] = \frac{1}{2} * \frac{1}{2} * \frac{1}{2} = \frac{1}{8}. \implies \Pr[Y_i = 1] = \frac{7}{8},$$

$$\mathsf{E}\big[Y_i\big] = \mathsf{Pr}\big[Y_i = 0\big] * 0 + \mathsf{Pr}\big[Y_i = 1\big] * 1 = \frac{7}{8}.$$

 $\mathsf{E}[\# \text{ of clauses sat}] = \mathsf{E}[Y] = \sum_{i=1}^m \mathsf{E}[Y_i] = (7/8)m.$ 

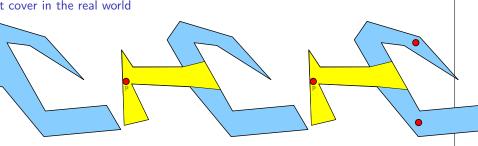

6/69

# **Biographical Notes**

The Max 3SAT remains hard in the "easier" variant of MAX 2SAT version, where every clause has 2 variables. It is known to be NP-Hard and approximable within 1.0741?, and is not approximable within 1.0476?. Notice, that the fact that MAX 2SAT is hard to approximate is surprising as 2SAT can be solved in polynomial time (!).

# Guarding an Art Gallery

Set cover in the real world

- 1. Given: floor plan of an art gallery.
- 2. Target: Place min # guards that see the whole polygon.
- 3. **Visibility polygon** at **p**: region inside polygon that **p** can see.
- 4. Example of **Set Cover**.
- 5. **NP-Hard**, no approximation currently known.

# Set cover

Example

#### Example

Consider set  $S = \{1, 2, 3, 4, 5\}$  and the family of subsets

$$\mathcal{F} = \left\{ \{1, 2, 3\}, \ \{2, 5\}, \ \{1, 4\}, \ \{4, 5\} \right\}.$$

Smallest cover of S is  $\mathcal{X}_{opt} = \{\{1,2,3\}, \{4,5\}\}.$ 

#### Set cover

#### **Set Cover**

Instance:  $(S, \mathcal{F})$ : **S** - a set of *n* elements  $\mathcal{F}$  - a family of subsets of  $\boldsymbol{S}$ , s.t.  $\bigcup_{X\in\mathfrak{F}}X=\mathsf{S}.$ **Question:** The set  $\mathfrak{X}\subseteq \mathfrak{F}$  such that  $\mathfrak{X}$  contains as few

sets as possible, and  $\mathfrak{X}$  covers  $\boldsymbol{S}$ . Formally,  $\bigcup_{\boldsymbol{x} \in \mathfrak{X}} \boldsymbol{X} = \boldsymbol{S}$ .

S: ground set

 $(S, \mathcal{F})$ : set system or a hypergraph. **Set Cover** is a minimization problem. **NP-Hard**.

#### Set cover

Greedy algorithm

```
GreedySetCover(S, \mathcal{F})
              \mathfrak{X}_0 \leftarrow \emptyset, U_0 \leftarrow S, i \leftarrow 0
              while U_i is not empty do
                      Y_i \leftarrow \text{set in } \mathcal{F} \text{ covering largest}
                             # of elements in U_i
                     X_{i+1} \leftarrow X_i \cup \{Y_i\}
                     U_{i+1} \leftarrow U_i \setminus Y_i
                     i \leftarrow i + 1
              return \chi_i.
```

- 1. **S**: set of **n** elements.
- 2. **F**: **m** sets.
- 3. Size of input  $\Omega(m+n)$  (and O(mn)).

# Set cover – Greedy algorithm

Analysis

- 1.  $\mathfrak{X}_{opt} = \{V_1, \dots, V_k\} \subseteq \mathfrak{F}$ : optimal solution.
- 2.  $U_i$ : elements not covered in beginning of ith iteration.
- 3.  $U_1 = S$ .
- 4.  $Y_i$ : set added to the cover in ith iteration.
- 5.  $\alpha_i = |Y_i \cap U_i|$ : # of new elements being covered.

Claim

We have  $\alpha_1 \geq \alpha_2 \geq \ldots \geq \alpha_k \geq \ldots \geq \alpha_m$ .

Proof.

If  $\alpha_i < \alpha_{i+1}$  then  $Y_{i+1}$  covers more elements than  $Y_i$  and we can exchange between them, and get a better set. A contradiction.

13/69

# Set cover – Greedy algorithm

Analysis continued

Using the claim

 $|U_i| \leq (1-1/k) |U_{i-1}| \leq (1-1/k)^i |U_0| = (1-1/k)^i n.$ 

Useful Fact

 $1-x \le e^{-x}.$ 

# Set cover – Greedy algorithm

Analysis continued

Claim

 $\alpha_i \geq |U_i|/k$ . Equivalently:  $|U_{i+1}| \leq (1-1/k)|U_i|$ .

Proof.

- 1. **k**: Size of optimal solution.
- 2. Opt solution:  $\mathcal{O} = \{O_1, \dots, O_k\}$  covers ground set **S**.
- 3.  $\Longrightarrow \forall i$   $U_i \subseteq S \subseteq \bigcup_{i=1}^k O_i$  elements of  $U_i$ .
- 4.  $\implies$  one set of opt covers  $\geq |U_i|/k$  of  $U_i$ .
- 5. greedy algorithm picks set  $Y_i$  with max cover.
- 6.  $\Longrightarrow Y_i$  covers  $\alpha_i \ge |U_i|/k$  (prev. not covered) elements.
- 7.  $|U_{i+1}| = |U_i| \alpha_i \leq (1 1/k) |U_i|$ .

14/69

# Set cover – Greedy algorithm

Analysis continued

**Theorem** 

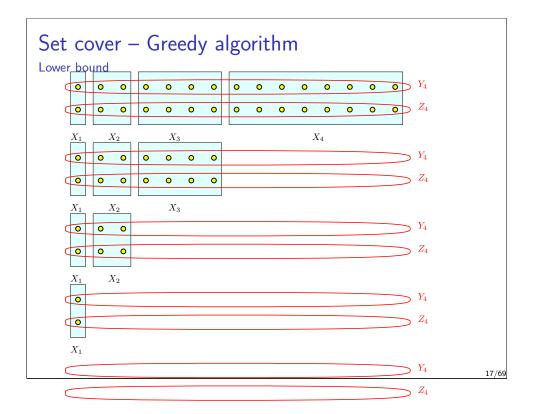

**GreedySetCover(S, \mathcal{F})** generates a cover of **S** using at most  $O(k \log n)$  sets of  $\mathcal{F}$ , k: size of the cover in opt solution. n = |S|

Proof.

In what round M is  $U_M$  empty?

For  $M = \lceil 2k \ln n \rceil$ :  $|U_M| \le \left(1 - \frac{1}{k}\right)^M n \le \exp\left(-\frac{1}{k}M\right) n$   $= \exp\left(-\frac{\lceil 2k \ln n \rceil}{k}\right) n \le \exp\left(-2 \ln n\right) n = \frac{1}{n} < 1,$  $\implies |U_M| = 0$ 

 $\implies$  Algorithm terminates before reaching Mth iteration.

# Weighted set cover – greedy algorithm

Analysis

- 1.  $U_i$ : set of elements not covered in beginning ith iteration.
- 2.  $U_1 = S$ .
- 3. Opt: optimal solution.
- 4. average optimal cost:  $\beta_i = \rho(\mathrm{Opt}) / |U_i|$ ,

# Weighted set cover

### Weighted Set Cover

Instance:  $(S, \mathcal{F}, \rho)$ :

**S**: a set of *n* elements

 $\mathfrak{F}$ : family subsets of **S**, s.t.  $\bigcup_{\mathbf{X} \in \mathfrak{F}} \mathbf{X} = \mathbf{S}$ .

 $\rho(\cdot)$ : A price function assigning price to each set in  $\mathcal{F}$ .

**Question:** The set  $\mathfrak{X}\subseteq \mathcal{F}$ , such that  $\mathfrak{X}$  covers **S**. Formally,  $\bigcup_{X\in \mathfrak{X}} X = S$ , and  $\rho(\mathfrak{X}) = \sum_{X\in \mathfrak{X}} \rho(X)$  is minimized.

- 1. **WGreedySetCover**: repeatedly picks set that pays the least cover each element it covers.
- 2.  $X \in \mathcal{F}$  covered t new elements, then the *average price* it pays per element  $\beta(X) = \rho(X)/t$ .
- 3. **WGreedySetCover**: picks the set with the lowest average price.

18/69

# Weighted set cover – greedy algorithm

Analysis – continued

#### Lemma

- (A)  $\beta_1 \leq \beta_2 \leq \cdots$
- (B) For i < j, we have if  $|U_j| > |U_i|/2$  then  $2\beta_i > \beta_j$ .

#### Proof.

(A)  $\beta_i = \frac{\rho(\mathrm{Opt})}{|U_i|}$ :  $\rho(\mathrm{Opt})$  is constant and  $|U_i|$  can only decrease

(B) 
$$|U_j| > |U_i|/2 \implies 2/|U_i| > 1/|U_j| \implies 2\rho(\mathrm{Opt})/|U_i| > \rho(\mathrm{Opt})/|U_j| \implies 2\beta_i > \beta_i$$

9/69

# Weighted set cover - greedy algorithm

Analysis – continued

#### Lemma

 $\beta_i = \rho(\mathrm{Opt}) / |U_i|$ : average optimal cost per uncovered element.

Let  $\mathrm{Opt} = \{X_1, \ldots, X_m\}$ , and  $s_j = |U_i \cap X_j|$ . Then  $\exists X_j \in \mathrm{Opt}$  with lower average cost:  $\rho(X_j) / s_j \leq \beta_i$ .

#### Proof.

$$\min_{j=1}^m \frac{\rho(X_j)}{s_j} \leq \frac{\sum_{j=1}^m \rho(X_j)}{\sum_{j=1}^m s_j} = \frac{\rho(\mathrm{Opt})}{\sum_{j=1}^m s_j} \leq \frac{\rho(\mathrm{Opt})}{|U_i|} = \beta_i.$$

#### Main Point

Greedy pays at most  $\beta_i$  per element in round i.

21 /60

# Weighted set cover – greedy algorithm

The result

#### Theorem

**WGreedySetCover** computes a  $O(\log n)$  approximation to the optimal weighted set cover solution.

#### Proof.

- 1. By Lemma: **WGreedySetCover** paid at most twice the Opt price to cover half the elements.
- 2. Now, repeat the argument on the remaining uncovered elements.
- 3. After  $O(\log n)$  such halving steps, all sets covered.
- 4. In each halving step, **WGreedySetCover** paid at most twice the opt cost.

# Weighted set cover – greedy algorithm

Analysis – continued

#### Lemma

k: first iteration  $|U_k| \le n/2$ . Total price of sets picked in iterations  $1 \dots k-1$ , is  $\le 2\rho(\text{Opt})$ .

#### Proof.

- 1.  $|U_i| > |U_1|/2$  for  $j = 2, \ldots, k-1$ ,
- 2. Earlier we showed: if  $|U_j| > |U_1|/2$  then  $2\beta_1 > \beta_j$ .
- 3.  $\beta_j = \frac{\rho(\mathrm{Opt})}{|U_j|}$  and  $|U_1| = n$  $\Rightarrow 2\rho(\mathrm{Opt})/n > \beta_j$  for  $j = 1, \dots, k-1$
- 4. We showed greedy pays at most  $\beta_j$  per element in round j  $\Rightarrow$  in rounds  $j = 1, \ldots, k 1$  greedy paid at most twice what opt paid per element.

22/6

# Part II

# Clustering

23/69

# Clustering

- 1. *unsupervised learning*: Given examples, partition them into classes of similar examples.
- 2. Example: Given webpage **X** about "The reality dysfunction", find all webpages on this topic (or closely related topics).
- 3. Webpage about "All quiet on the western front" should be in the same group as webpage as "Storm of steel".
- 4. Hope: All such webpages of interest in same cluster as **X**, if the clustering is good.

25/69

# Clustering – similarity measure

- 1. Input: A set of examples (points in high dim).
- 2. Example:
  - 2.1 Webpage W: *i*th coordinate to 1 if the word  $w_i$  appears in W.

We have 10,000 words care about.  $\emph{W}$  interpreted as a point  $\in \left\{0,1\right\}^{10,000}$ .

- 2.2 Let  $\boldsymbol{X}$  be the resulting set of  $\boldsymbol{n}$  points in  $\boldsymbol{d}$  dimensions.
- 3. Need similarity measure.
- 4. For example, Euclidean distance between points, where

$$\|p-q\| = \sqrt{\sum_{i=1}^{d} (p_i - q_i)^2},$$

where  $p = (p_1, \ldots, p_d)$  and  $q = (q_1, \ldots, q_d)$ 

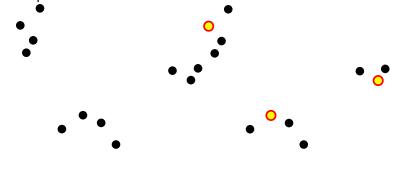

6/60

# Clustering – k center clustering

#### k center clustering problem

 ${m P}$ : set of  ${m n}$  cities, and distances between them. Build  ${m k}$  hospitals, s.t. max dist city from its closest hospital is min.

Example: k = 3

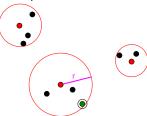

# Clustering – price

1. **price** of clustering of **P** by **S** is

$$\nu(P,S) = \max_{p \in P} d(p,S)$$

- 2. k-center problem.
  - 2.1 Find  $S \subseteq P$  s.t. |S| = k and  $\nu(P, S)$  minimized.
  - 2.2 Equivalently, find **k** smallest discs centered at input points...
  - $2.3 \dots$  cover all the points of  $\boldsymbol{P}$ .

# **k** Center Clustering

- 1. **k**-center clustering is **NP-Hard**...
- 2. ...even to approximate within a factor of (roughly) 1.8.
- 3. Formal definition...

#### *k*-center clustering

**Instance**: A set P of n points, a distance function d(p,q), for  $p,q \in P$ , satisfying the triangle inequality, and a parameter k.

**Question:** Find the subset **S** that realizes

$$r_{opt}(P, k) = \min_{S \subseteq P, |S| = k} \nu(P, S),$$

where  $\nu(P,S) = \max_{p \in P} d(p,S)$ 

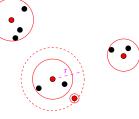

23/03

# **k**-center clustering - approximation algorithm

```
\begin{aligned} &\mathsf{AprxKCenter}(P,\ k) \\ &P = \{p_1, \dots, p_n\} \\ &S = \{p_1\},\ u_1 \leftarrow p_1 \\ &\mathsf{while}\ |S| < k\ \mathsf{do} \\ &i \leftarrow |S| \\ &\mathsf{for}\ j = 1 \dots n\ \mathsf{do} \\ &d_j \leftarrow \min(d_j, \mathsf{d}(p_j, u_i)) \\ &r_{i+1} \leftarrow \max(d_1, \dots, d_n) \\ &u_{i+1} \leftarrow \mathsf{point}\ \mathsf{of}\ P\ \mathsf{realizing}\ r_i \\ &S \leftarrow S \cup \{u_{i+1}\} \end{aligned}
```

# **k**-center clustering - approximation

1. Current solution with 3 centers... Add which center?

- 2. ...use bottleneck point.
- 3. Point furthest away from centers.
- 4. Find a new center that better serves this bottleneck point.
- 5. ...make it the next center.

30/69

# **k**-center clustering - approximation algorithm

- 1. Running time of **AprxKCenter** is **O(nk)**
- 2.  $r_{i+1}$ : the (minimum) radius of the i balls centered at  $u_1, \ldots, u_i$  covering P.
- 3.  $\exists p \in P$ :  $d(p, \{u_1, \ldots, u_i\}) = r_{i+1}$ .
- 4. Imagine run **AprxKCenter** one additional iteration. ... so  $r_{k+1}$  is well defined.

31/69

# k-center clustering approximation algorithm

Analysis

#### Lemma

 $r_2 \geq \ldots \geq r_k \geq r_{k+1}$ .

Proof...

#### Observation

The radius of the clustering generated by **AprxKCenter** is  $\mathbf{r}_{k+1}$ .

33/69

# **k**-center clustering approximation algorithm

Analysis – continued

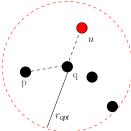

#### Lemma

 $r_{k+1} \leq 2r_{opt}(P, k)$ .  $r_{opt}(P, k)$ : radius of the opt with k balls.

#### Proof:

- 1.  $D_1, \ldots, D_k$ : k discs in opt sol.
- 2. **S**: **k** centers computed by **AprxKCenter**.
- 3. Suppose every disk  $D_i$  contains at least one point of  $S_{...}$
- 4. Then  $\forall p \in P$  distance to **S** is  $\leq 2r_{opt}(P, k)$ . That is,

$$d(p, u) \le d(p, q) + d(q, u) \le 2r_{opt}$$

34/69

# k-center clustering approximation algorithm

Analysis – continued

#### Proof continued

- 1. Otherwise,  $\exists x, y \in S$  contained in same ball  $D_i$  of Opt.
- 2. Let  $D_i$  be centered at a point q.
- 3. Claim:  $d(x, y) > r_{k+1}$ .
- 4. Suppose  $u_{\alpha} = x$ ,  $u_{\beta} = y$ ,  $\alpha < \beta$ .
- 5.  $d(x, y) \ge d(y, \{u_1, \ldots, u_{\beta-1}\}) \ge r_{\beta}$
- 6. By lemma  $r_{\beta} \geq r_{k+1}$ .  $\Longrightarrow$  claim holds
- 7. By triangle inequality:  $r_{k+1} < d(x, y) < d(x, q) + d(q, y) < 2r_{out}$ .

# **k**-center clustering approximation algorithm

#### Theorem

One can approximate the k-center clustering up to a factor of two, in time O(nk).

#### Proof.

**AprxKCenter**: approximation algorithm.

The approximation quality guarantee follows from the above lemma, since the furthest point of P from the k-centers computed is  $r_{k+1}$ , which is guaranteed to be at most  $2r_{opt}$ .

# Part III

### Subset Sum

37/60

# Subset Sum

#### **Subset Sum**

**Instance**:  $X = \{x_1, \dots, x_n\} - n$  integer positive numbers, t - target number **Question**:  $\exists$  subset of X s.t. sum of its elements is t?

Assume  $x_1, \ldots, x_n$  are all  $\leq n$ . Then this problem can be solved in

- (A) The problem is still **NP-Hard**, so probably exponential time.
- (B)  $O(n^3)$ .
- (C)  $2^{O(\log^2 n)}$ .
- (D)  $O(n \log n)$ .
- (E) None of the above.

8/69

# Subset Sum

#### **Subset Sum**

**Instance**:  $X = \{x_1, \dots, x_n\} - n$  integer positive numbers, t - target number **Question**:  $\exists$  subset of X s.t. sum of its elements is t?

```
SolveSubsetSum (X, t, M)
b[0...Mn] - \text{boolean array init to false.}
M: \text{Max value} \qquad \qquad // b[x] \text{ is true if } x \text{ can be realized}
// \text{by a subset of } X.
input numbers. b[0] \leftarrow \text{true.}
for i=1,\ldots,n do
for \ j=Mn \text{ down to } x_i \text{ do}
b[j] \leftarrow B[j-x_i] \vee B[j]
return B[t]
```

### Subset Sum

Efficient algorithm???

- 1. Algorithm solving **Subset Sum** in  $O(Mn^2)$ .
- 2. **M** might be prohibitly large...
- 3. if  $M = 2^n \implies$  algorithm is not polynomial time.
- 4. Subset Sum is NPC.
- 5. Still want to solve quickly even if **M** huge.
- 6. Optimization version:

#### **Subset Sum Optimization**

**Instance**: (X, t): A set X of n positive integers, and a target number t.

**Question:** The largest number  $\gamma_{opt}$  one can represent as a subset sum of  $\boldsymbol{X}$  which is smaller or equal to  $\boldsymbol{t}$ .

20 /60

#### Subset Sum

**2**-approximation

#### Lemma

- 1. (X, t); Given instance of **Subset Sum**.  $\gamma_{\text{opt}} \leq t$ : Opt.
- 2.  $\Longrightarrow$  Compute legal subset with sum  $\geq \gamma_{\rm opt}/2$ .
- 3. Running time  $O(n \log n)$ .

#### Proof.

- 1. Sort numbers in **X** in decreasing order.
- 2. Greedily add numbers from largest to smallest (if possible).
- 3. s: Generates sum.
- 4. u: First rejected number. s': sum before rejection.
- 5. s' > u > 0, s' < t, and  $s' + u > t \implies t < s' + u < s' + s' = 2s' \implies s' \ge t/2$ .

41/60

# Polynomial Time Approximation Schemes

- 1. Example: Approximation algorithm with running time  $O(n^{1/\varepsilon})$  is a PTAS.

  Algorithm with running time  $O(1/\varepsilon^n)$  is not.
- 2. Fully polynomial...

# Definition ( )

An approximation algorithm is *fully polynomial time* approximation scheme (FPTAS) if it is a PTAS, and its running time is polynomial both in n and  $1/\varepsilon$ .

- 3. Example: PTAS with running time  $O(n^{1/\epsilon})$  is not a FPTAS.
- 4. Example: PTAS with running time  $O(n^2/\varepsilon^3)$  is a FPTAS.

# Polynomial Time Approximation Schemes

Definition (

PROB: Maximization problem.

 $\varepsilon > 0$ : approximation parameter.

 $\mathcal{A}(I,\varepsilon)$  is a *polynomial time approximation scheme* (PTAS) for PROB:

- 1.  $\forall I$ :  $(1-\varepsilon) \left| \mathsf{opt}(I) \right| \leq \left| \mathcal{A}(I,\varepsilon) \right| \leq \left| \mathsf{opt}(I) \right|$ ,
- 2. |**opt(**/)|: opt price,
- 3.  $|\mathcal{A}(I,\varepsilon)|$ : price of solution of  $\mathcal{A}$ .
- 4.  $\mathcal{A}$  running time polynomial in  $\mathbf{n}$  for fixed  $\varepsilon$ .

For minimization problem:

$$|\mathsf{opt}(I)| \leq |\mathcal{A}(I,\varepsilon)| \leq (1+\varepsilon)|\mathsf{opt}(I)|$$
.

42/69

# Approximating Subset Sum

# **Subset Sum Approx**

**Instance**:  $(X, t, \varepsilon)$ : A set X of n positive integers, a target number t, and parameter  $\varepsilon > 0$ .

Question: A number z that one can represent as a subset sum of X, such that  $(1 - \varepsilon)\gamma_{\rm opt} \le z \le \gamma_{\rm opt} \le t$ .

43/69

# Approximating Subset Sum

Looking again at the exact algorithm

```
\begin{aligned} &\textbf{ExactSubsetSum}(\textbf{S}, \ t) \\ & & n \leftarrow |\textbf{S}| \\ & P_0 \leftarrow \{0\} \\ & \textbf{for } i = 1 \dots n \ \textbf{do} \\ & & P_i \leftarrow P_{i-1} \cup (P_{i-1} + x_i) \\ & & \texttt{Remove from } P_i \ \texttt{all elements} > t \end{aligned}
```

- 1.  $S = \{a_1, \ldots, a_n\}$  $x + S = \{a_1 + x, a_2 + x, \ldots a_n + x\}$
- 2. Lists might explode in size.

45/69

### Trim the lists...

```
 \begin{array}{c} \mathsf{Trim}(L',\delta) \\ L \leftarrow \mathsf{Sort}(L') \\ L = \langle y_1 \dots y_m \rangle \\ \mathit{curr} \leftarrow y_1 \\ L_{out} \leftarrow \{y_1\} \\ \mathsf{for} \ i = 2 \dots m \ \mathsf{do} \\ \mathsf{if} \ y_i > \mathit{curr} \cdot (1+\delta) \\ \mathsf{Append} \ y_i \ \mathsf{to} \ L_{out} \\ \mathit{curr} \leftarrow y_i \\ \mathsf{return} \ L_{out} \\ \end{array}
```

```
 \begin{array}{l} \mathsf{ApproxSubsetSum}(\mathsf{S},\ t) \\ //\ \mathcal{S} = \{x_1, \dots, x_n\}, \\ //\ \ x_1 \leq x_2 \leq \dots \leq x_n \\ n \leftarrow |\mathcal{S}|,\ L_0 \leftarrow \{0\},\ \delta = \varepsilon/2n \\ \mathsf{for}\ i = 1 \dots n\ \mathsf{do} \\ E_i \leftarrow L_{i-1} \cup (L_{i-1} + x_i) \\ L_i \leftarrow \mathsf{Trim}(E_i, \delta) \\ \mathsf{Remove}\ \mathsf{from}\ L_i\ \mathsf{elems} > t \,. \\ \\ \mathsf{return}\ \mathsf{largest}\ \mathsf{element}\ \mathsf{in}\ L_n \\ \end{array}
```

#### Trim the lists...

#### For two positive real $Trim(L', \delta)$ numbers z < y, the $L \leftarrow \mathsf{Sort}(L')$ humber **y** is a $L = \langle y_1 \dots y_m \rangle$ $\delta$ -approximation to z if $curr \leftarrow v_1$ $\frac{1}{1+\delta} \leq z \leq y.$ $L_{out} \leftarrow \{y_1\}$ for $i = 2 \dots m$ do if $y_i > curr \cdot (1 + \delta)$ Append $y_i$ to $L'_{out}$ Observation If $x \in L'$ then there exists a $curr \leftarrow v_i$ return L<sub>out</sub> number $y \in L_{out}$ such that $y < x < y(1 + \delta)$ , where $L_{out} \leftarrow \text{Trim}(L', \delta)$ .

# **Analysis**

- 1.  $E_i$  list generated by algorithm in ith iteration.
- 2.  $P_i$ : list of numbers (no trimming).

#### Claim

For any  $x \in P_i$  there exists  $y \in L_i$  such that  $y \le x \le (1 + \delta)^i y$ .

#### Proof

- 1. If  $x \in P_1$  then follows by observation above.
- 2. If  $x \in P_{i-1} \implies \text{(induction) } \exists y' \in L_{i-1} \text{ s.t.}$  $y' < x < (1 + \delta)^{i-1}y'.$
- 3. By observation  $\exists y \in L_i$  s.t.  $y \leq y' \leq (1 + \delta)y$ , As such,

$$y < y' < x < (1 + \delta)^{i-1}y' < (1 + \delta)^{i}y.$$

#### Proof continued

#### Proof continued

- 1. If  $x \in P_i \setminus P_{i-1} \implies x = \alpha + x_i$ , for some  $\alpha \in P_{i-1}$ .
- 2. By induction,  $\exists \alpha' \in \mathcal{L}_{i-1}$  s.t.  $\alpha' \leq \alpha \leq (1+\delta)^{i-1}\alpha'$ .
- 3. Thus,  $\alpha' + x_i \in E_i$ .
- 4.  $\exists x' \in L_i$  s.t.  $x' < \alpha' + x_i < (1 + \delta)x'$ .
- 5. Thus,

$$x' \leq \alpha' + x_i \leq \alpha + x_i = x \leq (1+\delta)^{i-1}\alpha' + x_i \leq (1+\delta)^{i-1}(\alpha' + x_i) \leq (1+\delta)^{i}x'.$$

# Running time of ApproxSubsetSum

#### Observation

In a list generated by **Trim**, for any number x, there are no two numbers in the trimmed list between x and  $(1 + \delta)x$ .

#### Lemma

$$|L_i| = O((n/\varepsilon^2) \log n)$$
, for  $i = 1, \ldots, n$ .

# Running time of ApproxSubsetSum

#### Lemma

For  $x \in [0, 1]$ , it holds  $\exp(x/2) \le (1 + x)$ .

#### Lemma

For  $0 < \delta < 1$ , and x > 1, we have

$$\log_{1+\delta} x \le \frac{2 \ln x}{\delta} = O\left(\frac{\ln x}{\delta}\right).$$

See notes for a proof of lemmas.

50/69

# Running time of ApproxSubsetSum

#### Proof.

- 1.  $L_{i-1} + x_i \subseteq [x_i, ix_i]$ .
- 2. Trimming  $L_{i-1} + x_i$  results in list of size

$$\log_{1+\delta} \frac{i x_i}{x_i} = O\left(\frac{\ln i}{\delta}\right) = O\left(\frac{\ln n}{\delta}\right),\,$$

3. Now,  $\delta = \varepsilon/2n$ , and

$$|L_i| \leq |L_{i-1}| + O\left(\frac{\ln n}{\delta}\right) \leq |L_{i-1}| + O\left(\frac{n \ln n}{\varepsilon}\right)$$

$$= O\left(\frac{n^2 \log n}{\varepsilon}\right).$$

# Running time of ApproxSubsetSum

#### Lemma

The running time of **ApproxSubsetSum** is  $O(\frac{n^3}{\varepsilon} \log^2 n)$ .

#### Proof.

- 1. Running time of **ApproxSubsetSum** dominated by total length of  $L_1, \ldots, L_n$ .
- 2. Above lemma implies  $\sum_{i} |L_{i}| = O\left(\frac{n^{3}}{\varepsilon} \log n\right)$ .
- 3. Trim sorts lists. *i*th iteration R.T.  $O(|L_i| \log |L_i|)$ .
- 4. Overall, R.T.  $O(\sum_i |L_i| |L_i|) = O(\frac{n^3}{\varepsilon} \log^2 n)$ .

# ApproxSubsetSum

#### Theorem

**ApproxSubsetSum** returns  $u \leq t$ , s.t.

$$\frac{\gamma_{\mathrm{opt}}}{1+\varepsilon} \leq u \leq \gamma_{\mathrm{opt}} \leq t$$
,

 $\gamma_{\rm opt}$ : opt solution.

Running time is  $O((n^3/\varepsilon)\log^2 n)$ .

#### Proof.

- 1. Running time from above.
- 2.  $\gamma_{\text{opt}} \in P_n$ : optimal solution.
- 3.  $\exists z \in L_n$ , such that  $z \leq \text{opt} \leq (1 + \delta)^n z$
- 4.  $(1+\delta)^n=(1+\varepsilon/2n)^n\leq \exp\left(\frac{\varepsilon}{2}\right)\leq 1+\varepsilon$ , since  $1+x\leq e^x$  for x>0.
- 5.  $\gamma_{\rm opt}/(1+\varepsilon) \le z \le {\rm opt} \le t$ .
