(Clarkson '87)
Cutting Lemma Given n lines L in \mathbb{R}^2 ,
 can cut \mathbb{R}^2 into $O(n^2)$ cells $\leftarrow O(n^d)$
 s.t. each cell intersects $\leq \frac{n}{7}$ lines.

$\Rightarrow O(n^{d+\epsilon})$ space, $O(\log n)$ time

(Matousek '91)
Partition Thm Given n pts P in \mathbb{R}^2 ,
 can partition into t subsets P_1, \dots, P_t
 each with $\sim \frac{n}{t}$ pts &
 find t cells $\Delta_1, \dots, \Delta_t$ with $P_i \subseteq \Delta_i$
 s.t. any line crosses $O(\sqrt{t})$ cells $\leftarrow O(t^{1-1/d})$

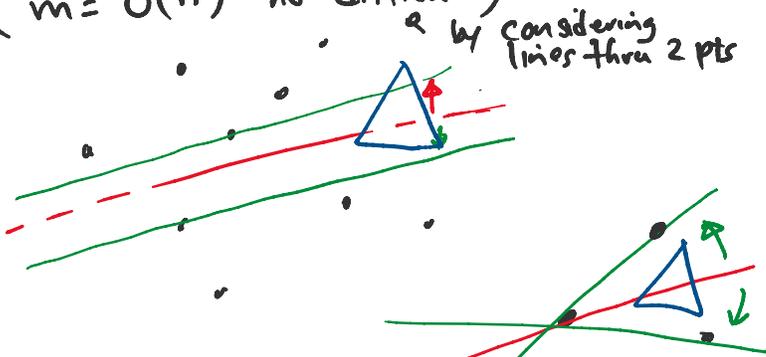

$\Rightarrow O(n)$ space
 $O(\sqrt{n \log^{O(1)} n})$ time
 $n^{1-1/d}$

Proof of Partition Thm:

{ Suffices to prove crossing #
 for a finite set L of "test" lines

($m = O(n^2)$ not difficult)
 by considering lines thru 2 pts

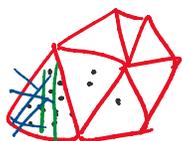

(with more work,
 can reduce $m = O(\epsilon)$)

(with more work,
can reduce $m = O(t)$) ✓

First Attempt:

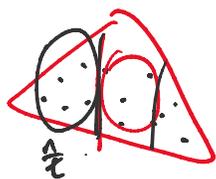

1. Apply Cutting Lemma to L with $r \approx \sqrt{t}$
 $\Rightarrow \# \text{ cells} = O(r^2) \approx O(t)$ $\uparrow t^{1/2}$
2. subdivide cells to ensure each with $\leq \frac{n}{t}$ pts

$\Rightarrow \leq t$ ^{extra} vertical cuts
 $\Rightarrow \# \text{ cells remains } O(t)$

Analysis: total crossings between lines & cells

$$O\left(t \cdot \frac{m}{r}\right) = O(m\sqrt{t})$$

$\# \text{ cells}$ \uparrow \uparrow $\# \text{ lines intersecting each cell}$

$\uparrow t^{1/2}$

\Rightarrow average $\#$ crossings per line = $O(\sqrt{t})$

BUT how to turn average to max?

idea - multiplicative weight update / (Welzl '88)
iterative reweighting

Matoušek's Alg'm:

define multiset \hat{L} , initialize to L , all multiplicities = 1
 \uparrow "weight" / "importance"

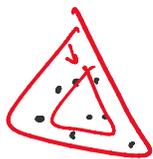

for $i = t, \dots, 1$ do:

// assume $\frac{n}{t}$ pts remaining

1. apply Cutting Lemma to \hat{L} with $r_i \approx \sqrt{i}$
 $\Rightarrow \# \text{ cells} = O(r_i^2) \approx i$
2. pick cell Δ_i with $\geq \frac{n}{t}$ pts
3. shrink Δ_i to have exactly $\frac{n}{t}$ pts P_i .

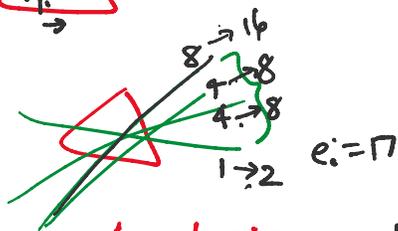

3. shrink Δ_i to have exactly $\frac{n}{t}$ pts P_i ,
 & remove P_i

4. for each $\ell \in L$ crossing Δ_i ,
 double multiplicity of ℓ in \hat{L}

e s.t. ℓ won't cross
 too many future cells

Analysis: before iteration i ,

let $m_i = |\hat{L}|$ (multiplicity included)

$e_i = |\{\ell \in \hat{L} : \ell \text{ crosses } \Delta_i\}|$

Know $e_i \leq \frac{m_i}{r_i} \approx \frac{m_i}{\sqrt{i}}$.

by Cutting Lem.

$$\Rightarrow m_{i+1} \leq m_i + e_i \leq \left(1 + \frac{1}{\sqrt{i}}\right) m_i$$

$$\Rightarrow m_{\text{final}} = m_0 \leq \left(1 + \frac{1}{\sqrt{t}}\right) \left(1 + \frac{1}{\sqrt{t-1}}\right) \dots \left(1 + \frac{1}{\sqrt{1}}\right) m$$

$$= m \prod_{i=1}^t \left(1 + \frac{1}{\sqrt{i}}\right)$$

$1+x \leq e^x$

$$\leq m \prod_{i=1}^t e^{1/\sqrt{i}}$$

$\sum_{i=1}^t 1/\sqrt{i} \approx O(\sqrt{t})$

$$= m e^{\sum_{i=1}^t \frac{1}{\sqrt{i}}} \approx \underline{m e^{O(\sqrt{t})}}$$

But $m_{\text{final}} = \sum_{\ell \in L} (\text{final multiplicity of } \ell)$

$$= \sum 2 \quad (\text{crossing\# of } \ell)$$

ℓ ∈ L

∀ ℓ ∈ L,

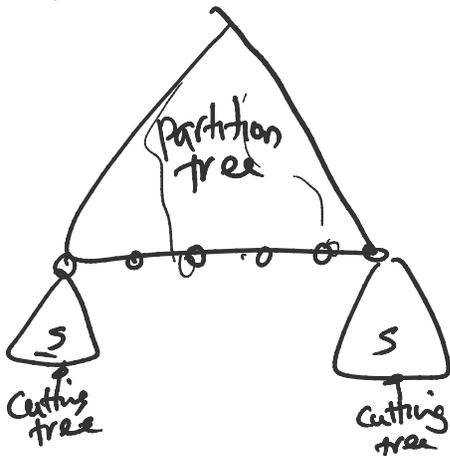

$$\text{crossing \# of } \ell \leq \log_2 m_{\text{trial}} \\ = O(\log m + \sqrt{t})$$

$$O(t^{1-1/d})$$

□

Rmk - if t is const,
 $O(n)$ time.

Consequences - space/time tradeoff

build partition tree
 when # pts $\leq s$,
 build cutting tree

$$\Rightarrow \text{space } O\left(n + \frac{n}{s} \cdot s^{2t\epsilon}\right)$$

$$= O(n s^{1+\epsilon})$$

$$\approx O(m) \quad \left(\text{set } s \approx \frac{m}{n}\right)$$

hide n^ϵ factors

query time

$$O\left(\left(\frac{n}{s}\right)^{\frac{1}{2}+\epsilon} \log s\right)$$

$$\approx O^*\left(\frac{n}{\sqrt{m}}\right)$$
