```
float bmi_si(float hcm, float kg){
    return kg / (hcm/100 * hcm/100);
}

float bmi_usa(float hin, float lbs){
    return lbs / (hin * hin) * 703;
}
```

```
float bmi(float ht, float wt, bool si=false){
    float val = wt/(ht*ht);
    if (si)
        return val*10000;
    else
        return val*703;
}
```

```
float bmi_si(float hcm, float kg){
    return kg / (hcm/100 * hcm/100);
}

float bmi_usa(float hin, float lbs){
    return lbs / (hin * hin) * 703;
}
```

C: Write two functions and use appropriate one depending on units at hand.

```
float bmi(float ht, float wt, bool si=false){
    float val = wt/(ht*ht);
    if (si)
        return val*10000;
    else
        return val*703;
}
```

```
float bmi_si(float hcm, float kg){
    return kg / (hcm/100 * hcm/100);
}

float bmi_usa(float hin, float lbs){
    return lbs / (hin * hin) * 703;
}
```

**C:** Write two functions and use appropriate one depending on units at hand.

C++: Write one function which can accept an optional flag for the rare case an European reports their weight and height in centimeters and kilograms

```
float bmi(float ht, float wt, bool si=false){
   float val = wt/(ht*ht);
   if (si)
      return val*10000;
   else
      return val*703;
}
```

```
float bmi_si(float hcm, float kg){
    return kg / (hcm/100 * hcm/100);
}

float bmi_usa(float hin, float lbs){
    return lbs / (hin * hin) * 703;
}
```

**C:** Write two functions and use appropriate one depending on units at hand.

C++: Write one function which can accept an optional flag for the rare case an European reports their weight and height in centimeters and kilograms

```
float bmi(float ht, float wt, bool si=false){
    float val = wt/(ht*ht);
    if (si)
        return val*10000;
        Default value is false
    else
        return val*703;
}
```

```
# include <iostream>
int main(){
  int *p;

  // Allocating an integer's worth of space
  p = new int;

  .
  .
  .
  // Deallocating
  delete p;
}
```

C C++

```
# include <iostream>
int main(){
  int *p;

  // Allocating an integer's worth of space
  p = new int;

  .
  .
  .
  // Deallocating
  delete p;
}
```

```
# include <iostream>
int main(){
  int *p;

  // Allocating an integer's worth of space
  p = new int;

  .
  .
  .// Deallocating
  delete p;
}
```

C	C++
Dynamic allocation is accomplished by malloc	Dynamic allocation is accomplished by new
Deallocation accomplished by free	Deallocation accomplished by delete

```
# include <iostream>
int main(){
  int *p;

  // Allocating an integer's worth of space
  p = new int;

  .
  .
  .
  // Deallocating
  delete p;
}
```

C	C++
Dynamic allocation is accomplished by malloc	Dynamic allocation is accomplished by new
Deallocation accomplished by free	Deallocation accomplished by delete
Both malloc and free are library functions	Both new and delete are keyword/operators

```
# include <iostream>
int main(){
  int *p;

  // Allocating an integer's worth of space
  p = new int;

  .
  .
  .
  // Deallocating
  delete p;
}
```

## Function overloading

 C++ allows multiple functions with the same name but different parameters.

### Function overloading

 C++ allows multiple functions with the same name but different parameters.

```
double volume(float r) {
  return 22.0/7*r*r*r*4/3;
}

double volume(float r, float l) {
  return 22.0/7*r*r*l;
}

double volume(float w, float h, float l) {
  return width * height * length;
}
```

## Function overloading

- C++ allows multiple functions with the same name but different parameters.
- Note: The return value cannot be different

```
double volume(float r) {
  return 22.0/7*r*r*r*4/3;
}

double volume(float r, float 1) {
  return 22.0/7*r*r*1;
}

double volume(float w, float h, float 1) {
  return width * height * length;
}
```

```
struct student{
    char name[74];
    unsigned long UIN;
    unsigned int year;
    float GPA;
};
```

```
struct student{
    char name[74];
    unsigned long UIN;
    unsigned int year;
    float GPA;
};
```

```
class Student{
    char name[74];
    unsigned long UIN;
    unsigned int year;
    float GPA;
};
```

```
struct student{
    char name[74];
    unsigned long UIN;
    unsigned int year;
    float GPA;
};
```

```
struct student{
    char name[74];
    unsigned long UIN;
    unsigned int year;
    float GPA;
};
```

```
struct student{
    char name[74];
    unsigned long UIN;
    unsigned int year;
    float GPA;
};
```

```
struct student{
    char name[74];
    unsigned long UIN;
    unsigned int year;
    float GPA;
};
```

```
struct student{
    char name[74];
    unsigned long UIN;
    unsigned int year;
    float GPA;
};
```

```
Student::Student(char const *name,
                 unsigned int UIN,
                 unsigned int year,
                 float GPA) {
  strcpy(this->name, name);
  this->UIN = UIN;
  this->year = year;
  this->GPA = GPA;
float Student::get GPA(){
 return this->GPA;
char const * Student::get name(){
  return this->name;
```

```
struct student{
    char name[74];
    unsigned long UIN;
    unsigned int year;
    float GPA;
};
```

```
Student::Student(char const *name,
                 unsigned int UIN,
                 unsigned int year,
                 float GPA) {
 strcpy(this->name, name);
  this->UIN = UIN;
  this->year = year;
 this->GPA = GPA;
float Student::get GPA(){
 return this->GPA;
char const * Student::get name(){
  return this->name;
```

```
struct student{
    char name[74];
    unsigned long UIN;
    unsigned int year;
    float GPA;
};
```

```
Student::Student(char const *name,
                 unsigned int UIN,
                 unsigned int year,
                 float GPA) {
 strcpy(this->name, name);
 this->UIN = UIN;
 this->year = year;
 this->GPA = GPA;
float Student::get GPA(){
 return this->GPA;
char const * Student::get name(){
  return this->name;
void Student::set GPA(float gpa){
 this->GPA = qpa;
```

### Operator overloading

```
int main(){
  Complex c1 = Complex(2, 4);
  Complex c2 = Complex(3, -5);
  Complex c3 = c1 + c2;
}
```

## Operator overloading

```
#include<iostream>
using namespace std;
class Complex{
  double real;
  double imag;
public:
  Complex(double real, double imag){
    this->real = real;
    this->imag = imag;
  void print(){
    cout<<"(" <<this->real<<" + "<<this->imag<<")";</pre>
Complex operator+(Complex c){
    return Complex(this->real + c.real, this->imag + c.imag);
};
```

```
int main(){
  Complex c1 = Complex(2, 4);
  Complex c2 = Complex(3, -5);
  Complex c3 = c1 + c2;
}
```

## Operator overloading

```
#include<iostream>
                                                         int main(){
using namespace std;
                                                           Complex c1 = Complex(2, 4);
                                                           Complex c2 = Complex(3, -5);
class Complex{
                                                           Complex c3 = c1 + c2;
  double real;
  double imag;
public:
  Complex(double real, double imag){
    this->real = real;
    this->imag = imag;
  void print(){
    cout<<"(" <<this->real<<" + "<<this->imag<<")";</pre>
Complex operator+(Complex c){
    return Complex(this->real + c.real, this->imag + c.imag);
```

Reference is yet another addition to the C/C++ zoo.

```
int val = 10;    // normal variable
int *ptr = &val; // & to get address, * to indicate pointer
```

Reference is yet another addition to the C/C++ zoo.

```
int val = 10;    // normal variable
int *ptr = &val; // & to get address, * to indicate pointer
int &ref = val;    // & to declare reference to val
```

Reference is yet another addition to the C/C++ zoo.

```
int val = 10;    // normal variable
int *ptr = &val; // & to get address, * to indicate pointer
int &ref = val;    // & to declare reference to val
```

- Reference is yet another addition to the C/C++ zoo.
- Key difference: A pointer is still a variable that takes up memory whereas a reference need not (C++ standard leaves it unspecified).

```
int val = 10;    // normal variable
int *ptr = &val; // & to get address, * to indicate pointer
int &ref = val;    // & to declare reference to val
```

- Reference is yet another addition to the C/C++ zoo.
- **Key difference**: A pointer is *still a variable* that takes up memory whereas a reference need not (C++ standard leaves it unspecified).
  - Think of it as an alias for a variable.

```
int val = 10;    // normal variable
int *ptr = &val; // & to get address, * to indicate pointer
int &ref = val;    // & to declare reference to val
```

- Reference is yet another addition to the C/C++ zoo.
- **Key difference**: A pointer is *still a variable* that takes up memory whereas a reference need not (C++ standard leaves it unspecified).
  - Think of it as an alias for a variable.
- If you remember the key difference then rest of the behavior is logical.

Pointer Reference

	Pointer	Reference
Memory address	Has memory allocated for it	May not have memory allocated for it

	Pointer	Reference
Memory address	Has memory allocated for it	May not have memory allocated for it
Function	Stores the memory address of variable	Acts as an <i>alias</i> for a variable

	Pointer	Reference
Memory address	Has memory allocated for it	May not have memory allocated for it
Function	Stores the memory address of variable	Acts as an <i>alia</i> s for a variable
Initialization/ reassignment	Can be declared, initialized and also reassigned	Initialized on declaration and cannot be reassigned

	Pointer	Reference
Memory address	Has memory allocated for it	May not have memory allocated for it
Function	Stores the memory address of variable	Acts as an <i>alias</i> for a variable
Initialization/ reassignment	Can be declared, initialized and also reassigned	Initialized on declaration and cannot be reassigned
Null value	Can be assigned the NULL pointer	Cannot be assigned a NULL value

	Pointer	Reference
Memory address	Has memory allocated for it	May not have memory allocated for it
Function	Stores the memory address of variable	Acts as an <i>alia</i> s for a variable
Initialization/ reassignment	Can be declared, initialized and also reassigned	Initialized on declaration and cannot be reassigned
Null value	Can be assigned the NULL pointer	Cannot be assigned a NULL value
Dereferencing	Must use the * operator	Automatically dereferenced

	Pointer	Reference
Memory address	Has memory allocated for it	May not have memory allocated for it
Function	Stores the memory address of variable	Acts as an <i>alia</i> s for a variable
Initialization/ reassignment	Can be declared, initialized and also reassigned	Initialized on declaration and cannot be reassigned
Null value	Can be assigned the NULL pointer	Cannot be assigned a NULL value
Dereferencing	Must use the * operator	Automatically dereferenced
Arrays	Can have array of pointers	Cannot create array of references

What will be the output?

```
#include <iostream>
using namespace std;
int main(){
  int val = 10;
  int *ptr = &val; // & to get address
  int &ref = val; // & to declare reference
  cout<<"val = "<<val<<endl;</pre>
  cout << "*ptr = "<< *ptr << endl;
  cout<<"ref = "<<ref<<endl;</pre>
  ref = 20;
  cout<<endl<<"val = "<<val<<endl;</pre>
  val = 30;
  cout<<"ref = "<<ref<<endl;</pre>
  cout<<"ptr = "<<ptr<<endl;</pre>
  ptr = &ref;
  cout<<"ptr = "<<ptr<<endl;</pre>
```

What will be the output?

```
#include <iostream>
using namespace std;
                                                          What will be the output?
int main(){
  int val = 10;
  int *ptr = &val; // & to get address
  int &ref = val; // & to declare reference
  cout<<"val = "<<val<<endl;</pre>
  cout << "*ptr = "<< *ptr << endl;
  cout<<"ref = "<<ref<<endl;</pre>
                                         Which variable(s) changed here?
  ref = 20;
  cout<<endl<<"val = "<<val<<endl;</pre>
  val = 30;
  cout<<"ref = "<<ref<<endl;</pre>
  cout<<"ptr = "<<ptr<<endl;</pre>
  ptr = &ref;
  cout<<"ptr = "<<ptr<<endl;</pre>
```

```
#include <iostream>
using namespace std;
                                                          What will be the output?
int main(){
  int val = 10;
  int *ptr = &val; // & to get address
  int &ref = val; // & to declare reference

                                        Which variable(s) changed here?
 ref = 20;
  cout<<endl<<"val = "<<val<<endl;</pre>
                                        What about here?
  val = 30;
  cout<<"ref = "<<ref<<endl;</pre>
  cout<<"ptr = "<<ptr<<endl; ←
                                        Are these addresses same or different?
  ptr = &ref;
  cout<<"ptr = "<<ptr<<endl; _</pre>
```

Mostly safety:

- Mostly safety:
  - No such thing as reference arithmetic & cannot reassign references (can do both to pointers).

- Mostly safety:
  - No such thing as reference arithmetic & cannot reassign references (can do both to pointers).
  - Paradigm: Use references for most use cases and use pointers only when you must.

- Mostly safety:
  - No such thing as reference arithmetic & cannot reassign references (can do both to pointers).
  - Paradigm: Use references for most use cases and use pointers only when you must.
- Passing around large objects to/via functions is simplified (for the programmer) with references:

- Mostly safety:
  - No such thing as reference arithmetic & cannot reassign references (can do both to pointers).
  - Paradigm: Use references for most use cases and use pointers only when you must.
- Passing around large objects to/via functions is simplified (for the programmer) with references:
  - Example later: copy constructors

```
void swap(int *a, int *b){
   int temp = *a;
   *a = *b;
   *b = temp;
}

void swap(int &a, int &b){
   int temp = a;
   a = b;
   b = temp;
}
```

```
void swap(int *a, int *b){
   int temp = *a;
   *a = *b;
   *b = temp;
}

void swap(int &a, int &b){
   int temp = a;
   a = b;
   b = temp;
}
```

```
int main(){
  int val1, val2;
  val1 = 10, val2 = 20;

  cout<<"val1 = "<<val1<<end1;
  cout<<"val2 = "<<val2<<end1;

  swap(&val1, &val2);
  cout<<end1<<"val1 = "<<val1<<end1;
  cout<<"val2 = "<<val2<<end1;

  swap(val1, val2);
  cout<<end1<, val2 = "<<val2<<end1;

  cout<<end1<<"val1 = "<<val1<<end1;
  cout<<end1<<=val1<=end1;
  cout<<end1<<=val1<=end1;
  cout<<end1<<=val1<=end1;
  cout<<end1<<=val1<<end1;
  cout<<=val2<<end1;
}</pre>
```

```
void swap(int *a, int *b){
    int temp = *a;
    *a = *b;
    *b = temp;
}

void swap(int &a, int &b){
    int temp = a;
    a = b;
    b = temp;
}
```

```
int main(){
  int val1, val2;
  val1 = 10, val2 = 20;

  cout<<"val1 = "<<val1<<end1;
  cout<<"val2 = "<<val2<<end1;

  swap(&val1, &val2);  Which function is called?
  cout<<end1<<"val1 = "<<val1<<end1;
  cout<<"val2 = "<<val2<<end1;

  swap(val1, val2);
  cout<<end1</pre>
  swap(val1 = "<<val1<<end1;
  cout<<end1<< "val1 = "<<val1<<end1;
  cout<<end1<< "val1 = "<<val1<<end1;
  cout<<end1<< "val1 = "<<val1<<end1;
  cout<<end1<< "val2 = "<<val2<<end1;
}</pre>
```

```
void swap(int *a, int *b){
    int temp = *a;
    *a = *b;
    *b = temp;
}

void swap(int &a, int &b){
    int temp = a;
    a = b;
    b = temp;
}
```

#### Can fail for uninitialized, dangling, or ill-formed pointers!

```
void swap(int *a, int *b){
   int temp = *a;
   *a = *b;
   *b = temp;
}
```

```
void swap(int &a, int &b){
   int temp = a;
   a = b;
   b = temp;
}
```

#### Can fail for uninitialized, dangling, or ill-formed pointers!

```
void swap(int *a, int *b){
   int temp = *a;
   *a = *b;
   *b = temp;
}
```

```
void swap(int &a, int &b){
  int temp = a;
  a = b;
  b = temp;
}
```

Less can go wrong with this version.

```
void swap(int *a, int *b){
    int temp = *a;
    *a = *b;
    *b = temp;
void swap(int &a, int &b){
    int temp = a;
    a = b;
    b = temp;
void swap(int a, int b){
    int temp = a;
    a = b;
    b = temp;
```

```
int main(){
  int val1, val2;
  val1 = 10, val2 = 20;
  cout << "val1 = " << val1 << endl;
  cout << "val2 = " << val2 << endl;
  swap(&val1, &val2); Which function is called?
  cout << endl << "val1 = " << val1 << endl;
  cout << "val2 = " << val2 << endl;
                              Which function is called?
  swap(val1, val2);
  cout << endl << "val1 = " << val1 << endl;
  cout << "val2 = " << val2 << endl;
```

```
void swap(int *a, int *b){
    int temp = *a;
    *a = *b;
    *b = temp;
void swap(int &a, int &b){
    int temp = a;
    a = b;
    b = temp;
void swap(int a, int b){
    int temp = a;
    a = b;
    b = temp;
```

```
int main(){
  int val1, val2;
  val1 = 10, val2 = 20;
  cout << "val1 = " << val1 << endl;
  cout << "val2 = " << val2 << endl;
  swap(&val1, &val2); Which function is called?
  cout<<endl<<"val1 = "<<val1<<endl;</pre>
  cout << "val2 = " << val2 << endl;
                             Which function is called?
  swap(val1, val2);
  cout << endl << "val1 = " << val1 << endl;
  cout << "val2 = " << val2 << endl;
```

What happens now?

```
void swap(int *a, int *b){
    int temp = *a;
    *a = *b;
    *b = temp;
void swap(int &a, int &b){
    int temp = a;
    a = b;
    b = temp;
void swap(int a, int b){
    int temp = a;
    a = b;
    b = temp;
```

```
int main(){
  int val1, val2;
  val1 = 10, val2 = 20;
  cout << "val1 = " << val1 << endl;
  cout << "val2 = " << val2 << endl;
  swap(&val1, &val2); Which function is called?
  cout<<endl<<"val1 = "<<val1<<endl;</pre>
  cout << "val2 = " << val2 << endl;
                             Which function is called?
  swap(val1, val2);
  cout << endl << "val1 = " << val1 << endl;
  cout << "val2 = " << val2 << endl;
```

**Overload resolution fails!** 

What happens now?

## Examples

```
void swap(int *a, int *b){
    int temp = *a;
    *a = *b;
    *b = temp;
void swap(int &a, int &b){
    int temp = a;
    a = b;
    b = temp;
void swap(int a, int b){
    int temp = a;
    a = b;
    b = temp;
```

```
int main(){
  int val1, val2;
  val1 = 10, val2 = 20;
  cout << "val1 = " << val1 << endl;
  cout << "val2 = " << val2 << endl;
  swap(&val1, &val2); Which function is called?
  cout<<endl<<"val1 = "<<val1<<endl;</pre>
  cout << "val2 = " << val2 << endl;
                             Which function is called?
  swap(val1, val2);
  cout << endl << "val1 = " << val1 << endl;
  cout << "val2 = " << val2 << endl;
```

**Overload resolution fails!** 

**Solution: Explicit casts** 

What happens now?

# Examples

```
void swap(int *a, int *b){
    int temp = *a;
    *a = *b;
    *b = temp;
void swap(int &a, int &b){
    int temp = a;
    a = b;
    b = temp;
void swap(int a, int b){
    int temp = a;
    a = b;
    b = temp;
```

```
int main(){
  int val1, val2;
  val1 = 10, val2 = 20;
  cout << "val1 = " << val1 << endl;
  cout << "val2 = " << val2 << endl;
  swap(&val1, &val2); Which function is called?
  cout<<endl<<"val1 = "<<val1<<endl;</pre>
  cout << "val2 = " << val2 << endl;
                             Which function is called?
  swap(val1, val2);
  cout << endl << "val1 = " << val1 << endl;
  cout << "val2 = " << val2 << endl;
```

Overload resolution fails!

**Solution: Explicit casts** 

What happens now?

Implement our old linked list using:

```
class Person{
  const char *name;
  unsigned int byear;

public:

  Person *next;
  Person(const char *name, unsigned int byear){
    this->name = name;
    this->byear = byear;
    this->next = NULL;
  }
};
```

Implement our old linked list using:

```
class Person{
  const char *name;
  unsigned int byear;

Person *next;
Person(const char *name, unsigned int byear){
    this->name = name;
    this->byear = byear;
    this->next = NULL;
}

These are private, if we want to be able to print our linked list will need to implement a print function.
```

Implement our old linked list using:

```
class Person{
  const char *name;
  unsigned int byear;
public:
  Person *next;
  Person(const char *name, unsigned int byear) {
    this->name = name;
    this->byear = byear;
    this->next = NULL;
  void print(){
      cout<< "(" << this->name << ", " << this->byear << ")" <<endl;</pre>
};
```

How to maintain head pointer, and add/remove functions?

- How to maintain head pointer, and add/remove functions?
  - Adopt the OOP way

- How to maintain head pointer, and add/remove functions?
  - Adopt the OOP way

```
class LinkedList{
Person *head;

public:
   LinkedList(){
    this->head = NULL;
   }
};
```

- How to maintain head pointer, and add/remove functions?
  - Adopt the OOP way

```
class LinkedList{
Person *head;

public:
   LinkedList(){
   this->head = NULL;
  }
};
```

 Basic functions to implement for a linked list?

- How to maintain head pointer, and add/remove functions?
  - Adopt the OOP way

```
class LinkedList{
Person *head;

public:
   LinkedList(){
    this->head = NULL;
   }
   void print_list();
```

- Basic functions to implement for a linked list?
  - Function to print list

- How to maintain head pointer, and add/remove functions?
  - Adopt the OOP way

```
class LinkedList{
Person *head;

public:
   LinkedList(){
    this->head = NULL;
   }
   void print_list();
   void add_at_head(Person &p);
};
```

- Basic functions to implement for a linked list?
  - Function to print list
  - Function to add at head

- How to maintain head pointer, and add/remove functions?
  - Adopt the OOP way

```
class LinkedList{
Person *head;

public:
   LinkedList(){
    this->head = NULL;
   }
   void print_list();
   void add_at_head(Person &p);
   void del_at_head();
};
```

- Basic functions to implement for a linked list?
  - Function to print list
  - Function to add at head
  - Function to remove from head

- How to maintain head pointer, and add/remove functions?
  - Adopt the OOP way

```
class LinkedList{
Person *head;

public:
   LinkedList(){
    this->head = NULL;
   }
   void print_list();
   void add_at_head(Person &p);
   void del_at_head();
};
```

- Basic functions to implement for a linked list?
  - Function to print list
  - Function to add at head
  - Function to remove from head

See Gitlab for full implementation!

```
class Dog{
  const char *name;

Private inheritance	No	No (inherited as private variables)	Yes (inherited as private variables)
Public inheritance	No	Yes (inherited as public variables)	Yes
<b>Protected</b> inheritance	No	Yes (inherited as protected variables)	Yes

### Inheritance rules

	Derived class has access to		
Inheritance	private members	public members	protected members
Private inheritance	No	No (inherited as private variables)	Yes (inherited as private variables)
Public inheritance	No	Yes (inherited as public variables)	Yes
<b>Protected</b> inheritance	No	Yes (inherited as protected variables)	Yes

#### Derived class constructor?

#### Derived class constructor?

```
class Dog: public Animal{
  bool nail clip;
public:
  Dog(const char *n, int b, int a, bool c){
    nail clip = c;
  void speak(){
    cout<<get name()<<": Woof!"<<endl;</pre>
};
class Cat: public Animal{
public:
  Cat(const char *n, int b, int a){
  };
  void speak(){
    cout<<get name()<<": Meow!"<<endl;</pre>
};
```

```
class Dog: public Animal{
  bool nail clip;
public:
  Dog(const char *n, int b, int a, bool c){
    nail clip = c;
  void speak(){
    cout<<get name()<<": Woof!"<<endl;</pre>
};
class Cat: public Animal{
public:
  Cat(const char *n, int b, int a){
  };
  void speak(){
    cout<<get name()<<": Meow!"<<endl;</pre>
};
```

How will Dog and Cat set their breed, name and age which are part of the Animal class and its private members?

```
class Dog: public Animal{
  bool nail_clip;
public:
  Dog(const char *n, int b, int a, bool c) : Animal(n, b, a) {
    nail clip = c;
  void speak(){
    cout<<get name()<<": Woof!"<<endl;</pre>
};
class Cat: public Animal{
public:
  Cat(const char*n, int b, int a) : Animal(n, b, a){
  };
  void speak(){
    cout<<get name()<<": Meow!"<<endl;</pre>
};
```

```
class Dog: public Animal{
  bool nail_clip;
public:
  Dog(const char *n, int b, int a, bool c) : Animal(n, b, a) {
    nail clip = c;
  void speak(){
    cout<<get name()<<": Woof!"<<endl;</pre>
};
class Cat: public Animal{
public:
  Cat(const char*n, int b, int a) : Animal(n, b, a) {
  };
  void speak(){
    cout<<get name()<<": Meow!"<<endl;</pre>
};
```

Will make sure to call the base class constructor first.

```
class Dog: public Animal{
  bool nail_clip;
public:
  Dog(const char *n, int b, int a, bool c) : Animal(n, b, a) {
    nail clip = c;
  void speak(){
    cout<<get name()<<": Woof!"<<endl;</pre>
};
class Cat: public Animal{
public:
  Cat(const char*n, int b, int a) : Animal(n, b, a) {
  };
  void speak(){
    cout<<get name()<<": Meow!"<<endl;</pre>
};
```

Will make sure to call the base class constructor first.

It is called *member initializer list* syntax!

```
#include <iostream>
using namespace std;
class Animal{
public:
  void eat(){
    cout << "I'm eating generic food." << endl;</pre>
};
class Cat : public Animal{
public:
  void eat(){
    cout << "I'm eating a mouse." << endl;</pre>
};
void eat lunch(Animal *a){
  a->eat();
```

```
#include <iostream>
using namespace std;
class Animal{
public:
  void eat(){
    cout << "I'm eating generic food." << endl;</pre>
};
class Cat : public Animal{
public:
  void eat(){
    cout << "I'm eating a mouse." << endl;</pre>
};
void eat lunch(Animal *a){
  a->eat();
```

```
int main(){
   Animal *anim = new Animal();
   Cat *bruno = new Cat();
   anim->eat();
   bruno->eat();

   eat_lunch(anim);
   eat_lunch(bruno);
}
```

```
#include <iostream>
using namespace std;
class Animal{
public:
  void eat(){
    cout << "I'm eating generic food." << endl;</pre>
};
class Cat : public Animal{
public:
  void eat(){
    cout << "I'm eating a mouse." << endl;</pre>
};
void eat lunch(Animal *a){
  a->eat();
```

```
int main(){
   Animal *anim = new Animal();
   Cat *bruno = new Cat();
   anim->eat();
   bruno->eat();

   eat_lunch(anim);
   eat_lunch(bruno);
}
```

Why didn't Bruno eat a mouse for lunch?

```
#include <iostream>
using namespace std;
class Animal{
public:
  void eat(){
    cout << "I'm eating generic food." << endl;</pre>
};
class Cat : public Animal{
public:
  void eat(){
    cout << "I'm eating a mouse." << endl;</pre>
};
void eat lunch(Animal *a){
  a->eat();
```

```
int main(){
   Animal *anim = new Animal();
   Cat *bruno = new Cat();
   anim->eat();
   bruno->eat();

   eat_lunch(anim);
   eat_lunch(bruno);
}
```

## Why didn't Bruno eat a mouse for lunch?

Need a way for the derived class to **override** the base class function,

... or ....

We will have to *overload* eat\_lunch for each new species!

```
#include <iostream>
using namespace std;
class Animal{
public:
  virtual void eat(){
    cout << "I'm eating generic food." << endl;</pre>
};
class Cat : public Animal{
public:
  void eat(){
    cout << "I'm eating a mouse." << endl;</pre>
};
void eat lunch(Animal *a){
  a->eat();
```

```
#include <iostream>
using namespace std;
class Animal{
public:
  virtual void eat(){
    cout << "I'm eating generic food." << endl;</pre>
};
class Cat : public Animal{
public:
  void eat(){
    cout << "I'm eating a mouse." << endl;</pre>
};
void eat lunch(Animal *a){
  a->eat();
```

 A virtual function is a member function in the base class that we expect to redefine in derived classes

```
#include <iostream>
using namespace std;
class Animal{
public:
  virtual void eat(){
    cout << "I'm eating generic food." << endl;</pre>
};
class Cat : public Animal{
public:
  void eat(){
    cout << "I'm eating a mouse." << endl;</pre>
};
void eat lunch(Animal *a){
  a->eat();
```

- A virtual function is a member function in the base class that we expect to redefine in derived classes
- What if your colleagues forget to override a virtual function? How to ensure it?

Pure virtual functions are used

#### Pure virtual functions are used

 if a function doesn't have any use in the base class

#### Pure virtual functions are used

- if a function doesn't have any use in the base class
- but the function must be implemented by all its derived classes

#### Pure virtual functions are used

- if a function doesn't have any use in the base class
- but the function must be implemented by all its derived classes

A pure virtual function doesn't have a function body and it ends with "=0"

#### Pure virtual functions are used

- if a function doesn't have any use in the base class
- but the function must be implemented by all its derived classes

A pure virtual function doesn't have a function body and it ends with "=0"

```
class Animal{
public:
    virtual void eat()=0;
};

class Cat : public Animal{
public:
    void eat(){
        cout << "I'm eating a mouse." << endl;
    }
};</pre>
```

#### Pure virtual functions are used

- if a function doesn't have any use in the base class
- but the function must be implemented by all its derived classes

A pure virtual function doesn't have a function body and it ends with "=0"

```
class Animal{
public:
    virtual void eat()=0;
};

class Cat : public Animal{
public:
    void eat(){
        cout << "I'm eating a mouse." << endl;
    }
};</pre>
```

Adding a pure virtual function turns a normal class to an *abstract* class!

Abstract class is a class that contains one or more pure virtual functions.

- Abstract class is a class that contains one or more pure virtual functions.
  - No objects of that abstract class can be created

- Abstract class is a class that contains one or more pure virtual functions.
  - No objects of that abstract class can be created
  - A pure virtual function that is not implemented in a derived class remains a pure virtual function, so the derived class is also an abstract class

- Abstract class is a class that contains one or more pure virtual functions.
  - No objects of that abstract class can be created
  - A pure virtual function that is not implemented in a derived class remains a pure virtual function, so the derived class is also an abstract class
  - An abstract class is intended as an interface to objects accessed through pointers and references (e.g. eat\_lunch function)

Recall that we could implement a Stack ADT with a linked list

- Recall that we could implement a Stack ADT with a linked list
  - Push: add at head of linked list

- Recall that we could implement a Stack ADT with a linked list
  - Push: add at head of linked list
  - Pop: remove from head + give popped value to caller

- Recall that we could implement a Stack ADT with a linked list
  - Push: add at head of linked list
  - Pop: remove from head + give popped value to caller
  - How can we do the second part?

```
class Person{
  const char *name;
  unsigned int byear;
public:
  Person *next;
  Person(const char *name, unsigned int byear);
  Person(const Person &p);
};
Person::Person(const Person &p){
    this->name = p.name;
    this->byear = p.byear;
    this->next = NULL;
```

```
Second constructor
class Person{
                         useful to copy an
  const char *name;
                        instance of Person.
  unsigned int byear;
public:
  Person *next;
  Person(const char /*name, unsigned int byear);
  Person(const Person &p);
};
Person::Person(const Person &p){
    this->name = p.name;
    this->byear = p.byear;
    this->next = NULL;
```

```
Second constructor
class Person{
                         useful to copy an
  const char *name;
                        instance of Person.
  unsigned int byear;
public:
  Person *next;
  Person(const char /*name, unsigned int byear);
  Person(const Person &p);
};
Person::Person(const Person &p){
    this->name = p.name;
    this->byear = p.byear;
    this->next = NULL;
```

Called pass by constant reference.

```
Second constructor
class Person{
                         useful to copy an
  const char *name;
                        instance of Person.
  unsigned int byear;
public:
  Person *next;
  Person(const char /*name, unsigned int byear);
  Person(const Person &p);
};
Person::Person(const Person &p){
    this->name = p.name;
    this->byear = p.byear;
    this->next = NULL;
```

Called pass by constant reference.

• Exercise: Can we appropriately modify the LinkedList class definition and create a derived Stack class from it?

```
class Person{
  const char *name;
   unsigned int byear;

public:
   Person *next;
   Person(const char *name, unsigned int byear);
   Person(const Person &p);
};

Person::Person(const Person &p){
    this->name = p.name;
    this->byear = p.byear;
    this->next = NULL;
```

Called pass by constant reference.

- Exercise: Can we appropriately modify the LinkedList class definition and create a derived Stack class from it?
- Stack should only expose the push and pop functions.

# Exercise - time permitting

- How to modify the LinkedList class?
  - Does add\_at\_head and del\_at\_head need to be public?
    - Can they be private?
  - When popping, we need access to head pointer to call copy constructor - can it still be private?

• What if we would like a *select* few functions to have access to the objects members?

- What if we would like a select few functions to have access to the objects members?
  - C++ lets you define *friend* functions in a class declaration.

- What if we would like a select few functions to have access to the objects members?
  - C++ lets you define friend functions in a class declaration.
  - These classes have access to all class members but are not class members themselves

- What if we would like a select few functions to have access to the objects members?
  - C++ lets you define friend functions in a class declaration.
  - These classes have access to all class members but are not class members themselves

```
class Box {
   double width;
   public:
      friend void printWidth( Box box );
      void setWidth( double wid);
};
// Member function definition
void Box::setWidth( double wid) {
   width = wid;
/* Note: printWidth() is not a member
function of any class */
void printWidth( Box box ) {
   /* Because printWidth() is a friend of Box,
      it can directly access any member of this
      class */
   cout << "Width of box : " << box.width <<endl;</pre>
```
