

ECE 220 Computer Systems & Programming

Yih-Chun Hu

adapted from material by Profs. Yuting Chen, Sanjay Patel, Volodymyr Kindratenko

Ways to Support I/O

- Port-Mapped I/O: separate address space, separate instructions to access I/O devices
 - Example: x86 IN, OUT instructions
- Memory-Mapped I/O: map I/O devices to regular memory, access with normal memory instructions

Key Concept: Abstraction

Create building blocks that are tightly specified.
Abstract away their details to a simple interface.
And then use them to build more complex things.

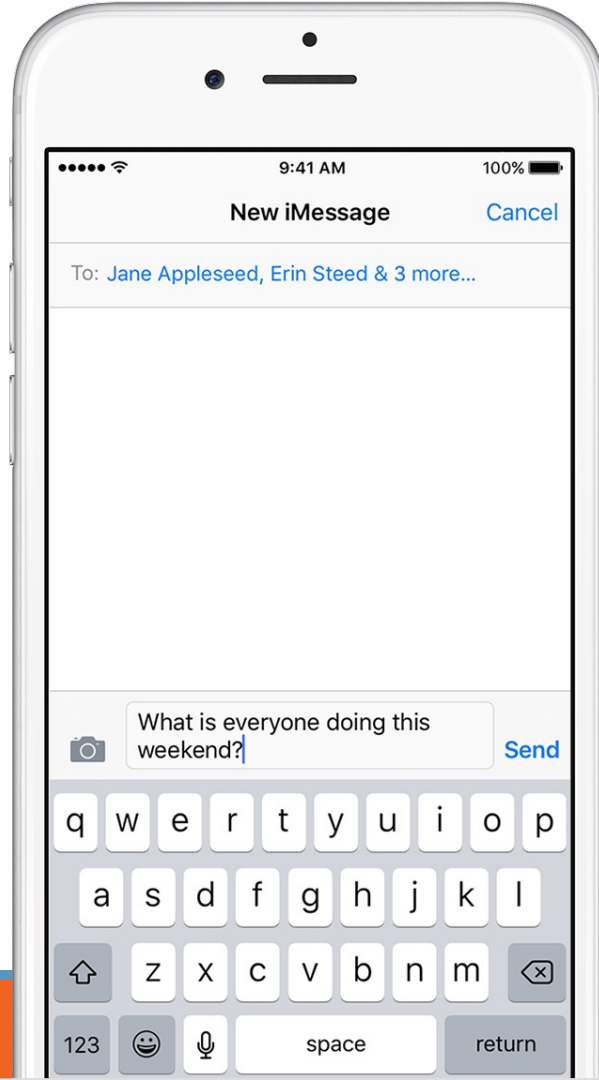

Then optimize the building blocks like crazy...

I/O is for interfacing between the physical world and digital world.

So what is the world's most commonly used digital interface?

....at least between a human and a digital system.

LC3 Memory: Memory mapped device registers

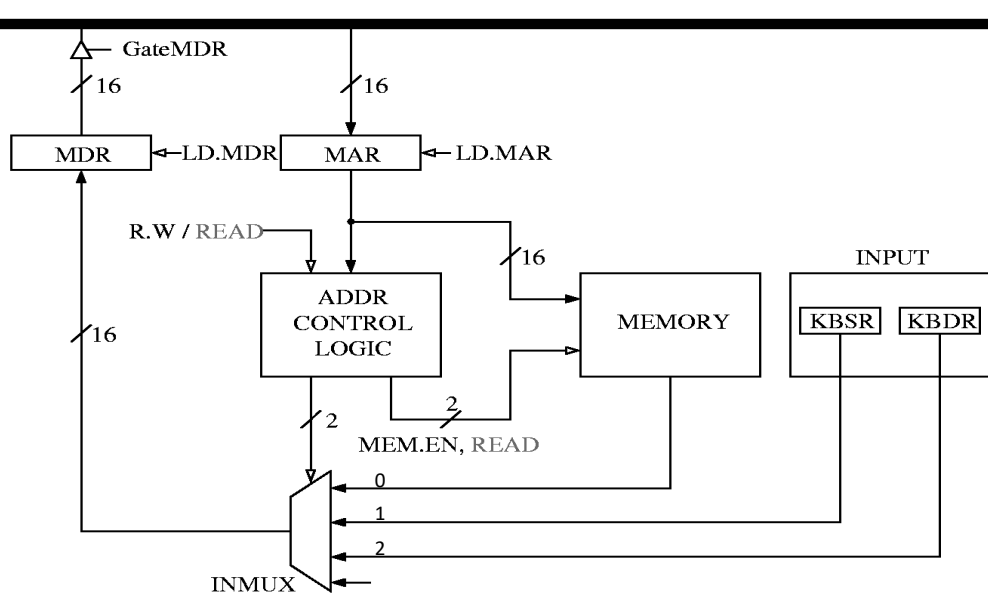

Address	Contents	Comments
x0000		; system space
...		
x3000		; user space
		; programs
		; and data
...		
xFE00	KBSR	; Device register
xFE02	KBDR	
xFE04	DSR	
xFE06	DDR	
...		
xFFFF		

These are the memory addresses to which the device registers (KBDR, etc.) are **mapped**

But the device registers physically are **separate** from the memory.

Memory-mapping device registers is a very common way to design interfaces for computing systems

Circuit for memory mapped Input

Conventional memory access: LD DR, addr

- $MAR \leftarrow \text{addr}$
- $MDR \leftarrow \text{MEM}[MAR]$
- $DR \leftarrow MDR$

Memory-mapped input access: LD DR, xFE02

- $MAR \leftarrow \text{xFE02}$
- $MDR \leftarrow \text{KBDR}$
- $DR \leftarrow MDR$

Basics of Interface Design

- Producer of data (finger at touchscreen) is working much much more slowly than consumer of that data (messaging app)
- We need to account for *asynchronous* operation
- We will use a simple consumer/producer handshake

Handshaking using KBDR and KBSR

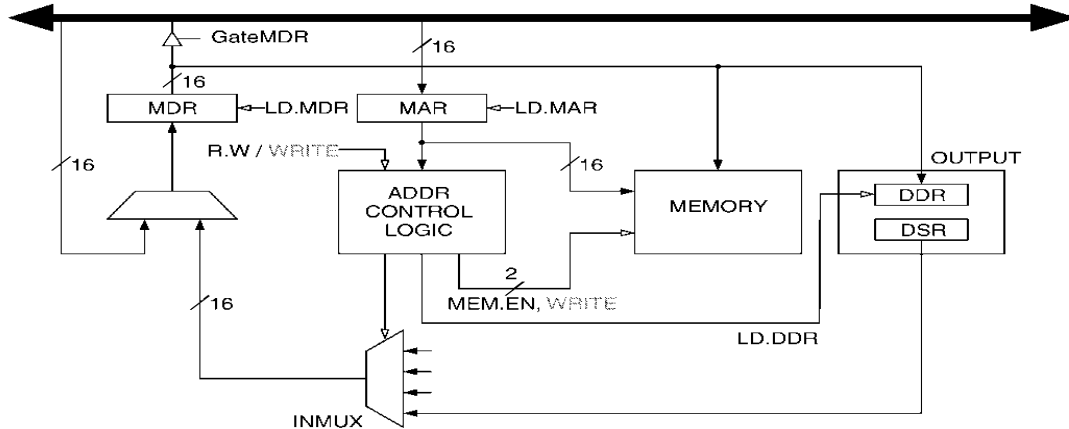

- When a char is typed by user in the keyboard
 - Its ASCII code is placed in KBDR[0:7]
 - KBSR[15] is set to 1 (ready bit)
 - Keyboard is disabled
- When KBDR is read by CPU
 - KBSR[15] is set to 0
 - Keyboard is enabled

This is part of the keyboard hardware.

Reading Input the right way

Circuit for memory mapped output

Conventional write: ST SR, addr

- $MAR \leftarrow \text{addr}$
- $MDR \leftarrow SR$
- $\text{Mem}[MAR] \leftarrow MDR$

Memory-mapped input access: ST SR, xFE06

- $MAR \leftarrow \text{xFE06}$
- $MDR \leftarrow SR$
- $DDR \leftarrow MDR$

Handshaking using DDR and DSR

- When display is ready for another char
 - DSR[15] is set to 1 (**ready bit**)
- When new char is written to DDR
 - DSR[15] is set to 0 and DDR[7:0] is displayed
 - Any other chars written to DDR are ignored

This is part of the display hardware.

Sending Character to Display

But wait...

- What's the system doing while it waits for me to touch the next key?
[hint: BRz p START...]
- If it takes me 0.5 sec, that's about 1 billion operations
- How can we do something useful?
