 $\begin{array}{cccc} \hline Review \\ \circ \bullet \bullet \bullet \bullet \bullet \end{array} & \mbox{DT Filtering} & \mbox{Sampling} & \mbox{Filtering} & \mbox{Interpolation} & \mbox{Rectangular Averager} & \mbox{Binary Differencer} & \mbox{Conclusions} & \mbox{cooco} & \mb$

A signal is sampled by measuring its value once every T_s seconds:

$$x[n] = x(t = nT_s)$$

The spectrum of the DT signal has components at $\omega = \frac{2\pi f}{F_s}$, and also at every $2\pi \ell + \omega$ and $2\pi \ell - \omega$, for every integer ℓ . Aliasing occurs unless $|\omega| \leq \pi$.

A CT signal y(t) can be created from a DT signal y[n] by interpolation:

$$y(t) = \sum_{n=-\infty}^{\infty} y[n]p(t - nT_s)$$

- $p(t) = rectangle \Rightarrow PWC$ interpolation
- $p(t) = triangle \Rightarrow PWL$ interpolation
- $p(t) = \operatorname{sinc}\left(\frac{\pi t}{T_s}\right) \Rightarrow$ perfectly bandlimited interpolation, y(t) has no spectral components above F_N

Convolution (finite impulse response filtering) is a generalization of weighted local averaging:

$$y[n] = h[n] * x[n] \equiv \sum_{m} x[m]h[n-m] = \sum_{m} x[n-m]h[m]$$

- If all samples of *h*[*n*] are positive, then it's a weighted local averaging filter
- If the samples of h[n] are positive for n > 0 and negative for n < 0 (or vice versa), then it's a weighted local differencing filter

• Tones in \rightarrow Tones out

$$\begin{aligned} x[n] &= e^{j\omega n} \to y[n] = H(\omega)e^{j\omega n} \\ x[n] &= \cos(\omega n) \to y[n] = |H(\omega)|\cos(\omega n + \angle H(\omega)) \\ x[n] &= A\cos(\omega n + \theta) \to y[n] = A|H(\omega)|\cos(\omega n + \theta + \angle H(\omega)) \end{aligned}$$

• where the Frequency Response is given by

$$H(\omega) = \sum_{m} h[m] e^{-j\omega m}$$

DT Filtering of CT Signals

$$x(t) \longrightarrow \boxed{A/D} \xrightarrow{x[n]} y[n] = h[n] * x[n] \xrightarrow{y[n]} D/A \longrightarrow y(t)$$

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Constraints:

- Assume that A/D and D/A use same F_s
- Assume $F_s \ge 2f_{\max}$
- Assume sinc interpolation

- If h[n] is a local averager, what's the relationship of y(t) to x(t)?
- If h[n] is a local differencer, what's the relationship of y(t) to x(t)?

- 4 Filtering
- **5** Interpolation
- 6 Rectangular Averager
- 7 Binary Differencer
- 8 Conclusions

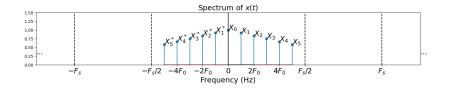

To start with, let's assume x(t) is periodic and bandlimited, so:

$$egin{aligned} & x(t) = \sum_{k=-N}^N X_k e^{j2\pi k F_0 t} \ & x[n] = \sum_{k=-N}^N X_k e^{jk\omega_0 n}, \end{aligned}$$

where $\omega_0 = \frac{2\pi F_0}{F_s}$, and $N = \lfloor \frac{F_s/2}{F_0} \rfloor$ is number of harmonics between 0 and the Nyquist frequency.

Review DT Filtering Sampling Filtering Interpolation Rectangular Averager Binary Differencer Conclusions Sampling of Periodic Bandlimited Signals

Now we know how to get from x(t) to x[n], assuming x(t) is periodic and bandlimited:

$$x(t) = \sum_{k=-N}^{N} X_k e^{j2\pi kF_0 t}$$
$$x[n] = \sum_{k=-N}^{N} X_k e^{jk\omega_0 n}$$

$$x(t) \xrightarrow{x[n]} y[n] = h[n] * x[n] \xrightarrow{y[n]} D/A \xrightarrow{\bullet} y(t)$$

Let's focus on just one of the harmonics of x(t):

$$x(t) = Xe^{j2\pi ft}$$

$$x[n] = Xe^{j\omega n}$$

$$y[n] = Ye^{j\omega n}$$

$$y(t) = Ye^{j2\pi ft}$$

Can we find the relationship between the two phasors Y and X?

・ロト ・ 目 ・ ・ ヨト ・ ヨ ・ うへつ

Relationship Between Y and X

Filtering

Review

DT Filtering

Remember that y[n] = x[n] * h[n], i.e.,

$$y[n] = \sum_{m=-\infty}^{\infty} h[m]x[n-m]$$

Interpolation

Rectangular Averager

Binary Differencer

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Conclusions

What happens if we plug in $x[n] = Xe^{j\omega n}$?

$$y[n] = \sum_{m=-\infty}^{\infty} h[m] X e^{j\omega(n-m)}$$
$$= X e^{j\omega n} \sum_{m=-\infty}^{\infty} h[m] e^{-j\omega m}$$
$$= X e^{j\omega n} H(\omega)$$

So $Y = H(\omega)X$, where $H(\omega)$ is the frequency response!

Review DT Filtering Sampling Filtering Interpolation Rectangular Averager Binary Differencer Conclusions 00000 000 0000 0000 00000 000000 00000 0000 Filtering Periodic Signals

Now let's generalize to the case when x(t) is any periodic bandlimited signal

$$x(t) = \sum_{k=-N}^{N} X_k e^{j2\pi kF_0 t}$$
$$x[n] = \sum_{k=-N}^{N} X_k e^{jk\omega_0 n}$$

Since the system is linear, adding inputs \Rightarrow add outputs. So the output is

$$y[n] = \sum_{k=-N}^{N} Y_k e^{jk\omega_0 n}, \qquad = \sum_{k=-N}^{N} H(k\omega_0) X_k e^{jk\omega_0 n},$$

... where $H(k\omega_0)$ is the frequency response of the system at frequency $k\omega_0$.

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ □ のへぐ

2 DT Filtering

3 Sampling

4 Filtering

- 5 Interpolation
- 6 Rectangular Averager
- 7 Binary Differencer

8 Conclusions

Remember, here's the overall system:

$$x(t) \longrightarrow \boxed{A/D} \begin{array}{c} x[n] \\ y[n] = h[n] * x[n] \\ \hline D/A \longrightarrow y(t)$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

 \ldots and remember that the D/A uses ideal bandlimited sinc interpolation.

Remember that the sinc is the function that perfectly reconstructs any signal below the Nyquist frequency:

$$y(t) = \sum_{n=-\infty}^{\infty} y[n] \operatorname{sinc} (\pi(t - nT_s))$$

= $\begin{cases} y[n] & t = nT_s \\ \text{bandlimited interpolation} & otherwise \end{cases}$

... where "bandlimited interpolation" means that y[n]'s spectrum for $-\pi < \omega < \pi$ is perfectly reconstructed by y(t)'s spectrum for $-\frac{F_s}{2} < f < \frac{F_s}{2}$, and that y(t) has no spectrum outside that range.

Putting it all together, we have:

$$\begin{aligned} x(t) &= \sum_{k=-N}^{N} X_k e^{j2\pi kF_0 t} \\ x[n] &= \sum_{k=-N}^{N} X_k e^{jk\omega_0 n}, \\ y[n] &= \sum_{k=-N}^{N} Y_k e^{jk\omega_0 n}, \\ y(t) &= \sum_{k=-N}^{N} Y_k e^{j2\pi kF_0 n}, \end{aligned}$$

where $\omega_0 = \frac{2\pi F_0}{F_s}$, and $N = \lfloor \frac{F_s/2}{F_0} \rfloor$, and $Y_k = H(k\omega_0)X_k$.

8 Conclusions

$$y[n] = \sum_{m} h[m] x[n-m]$$

Consider the case of the rectangular averager:

$$h[n] = \begin{cases} \frac{1}{N} & -\left(\frac{N-1}{2}\right) \le n \le \left(\frac{N-1}{2}\right) \\ 0 & \text{otherwise} \end{cases}$$

▲□▶ ▲□▶ ▲三▶ ▲三▶ 三三 のへで

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

When the input is low-frequency, the output of an averager is almost the same as the input:

When the input is high-frequency, the system averages over almost one complete period, so the output is close to zero:

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

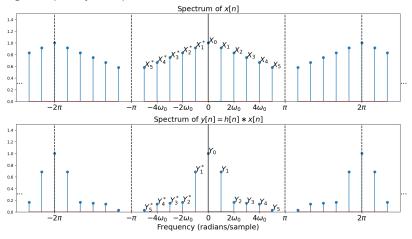

Review DT Filtering Sampling Filtering Interpolation Rectangular Averager Binary Differencer Conclusions Rectangular Averaging: General Case General Case General Case General Case

Remember the general form for the frequency response:

$$Y = X \sum_{m=-\infty}^{\infty} h[m] e^{-j\omega m}$$
$$= \frac{X}{N} \sum_{m=-(N-1)/2}^{(N-1)/2} e^{-j\omega m}$$
$$= \frac{X}{N} \left(1 + 2 \sum_{m=1}^{(N-1)/2} \cos(\omega m) \right)$$

- If ω is very small, all terms are positive, so the output is large.
- If ω is larger, then the summation includes both positive and negative terms, so the output is small.

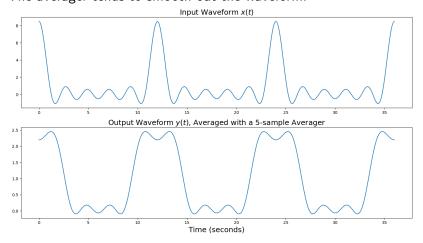

The averager retains low-frequency components, but reduces high-frequency components:

8 Conclusions

	DT Filtering 000		Rectangular Averager 0000000	
Con	clusions			

$$x(t) \xrightarrow{x[n]} y[n] = h[n] * x[n] \xrightarrow{y[n]} D/A \xrightarrow{\bullet} y(t)$$

If x(t) is periodic, then y(t) is also periodic with the same period but different Fourier Series coefficients:

$$\begin{aligned} x(t) &= \sum_{k=-N}^{N} X_k e^{j2\pi kF_0 t}, \qquad x[n] = \sum_{k=-N}^{N} X_k e^{jk\omega_0 n} \\ y[n] &= \sum_{k=-N}^{N} Y_k e^{jk\omega_0 n}, \qquad y(t) = \sum_{k=-N}^{N} Y_k e^{j2\pi kF_0 t} \end{aligned}$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ □臣 ○のへ⊙

The relationship between the Fourier series coefficients is given by the frequency response of the system:

$$Y = X \sum_{m} h[m] e^{-j\omega m}$$

- A rectangular averager is a low-pass filter: low-frequency signals pass through, but high-frequency signals are averaged out.
- A binary differencer is a high-pass filter: high-frequency signals pass through, but low-frequency signals are differenced out, especially the OHz component.
