Assigned: Monday, 11/2/2020; Due: Monday, 11/9/2020 Reading: Mohri, Pereira & Riley, Weighted Finite State Transducers in Speech Recognition, 2001

### Problem 5.1

The best-path algorithm for a WFSA is

• Initialize:

$$\delta_0(i) = \begin{cases} \bar{1} & i = \text{initial state} \\ \bar{0} & \text{otherwise} \end{cases}$$

• Iterate:

$$\delta_k(j) = \underset{t:n[t]=j,\ell[t]=s_k}{\text{best}} \delta_{k-1}(p[t]) \otimes w[t]$$
$$\psi_k(j) = \underset{t:n[t]=j,\ell[t]=s_k}{\text{argbest}} \delta_{k-1}(p[t]) \otimes w[t]$$

• Backtrace:

$$t_k^* = \psi(q_{k+1}^*), \qquad q_k^* = p[t_k^*]$$

where k is the number of input words that have been observed, and j is the state index. Unlike an HMM,  $\delta_k(j) = \bar{0}$  for most states at most times. We only need to keep track of  $\delta_k(j)$  and  $\psi_k(j)$  for (k, j) at which  $\delta_k(j) \neq \bar{0}$ .

Create a table:

- with columns indexed by  $k, 0 \le k \le 5$ ,
- for the utterance  $[s_1, \ldots, s_5] = [A, dog, is, very, hungry],$
- for the FSA shown above, whose transition weights are given in surprisal form.
- In each column: list the states j for which  $\delta_k(j) \neq \overline{0}$  ( $\delta_k(j) < \infty$ , since we're using surprisals).

- For each such state, list its  $\delta_k(j)$  (as a surprisal), and
- list its backpointer,  $\psi_k(j)$ , which should be a transition, in the format  $t = (p, \ell, w, n)$  showing the previous state, label, weight, and next state.

#### Problem 5.2

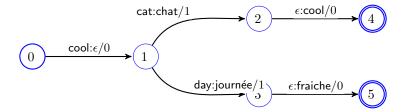

Show that if u, v, x, y, z are surprisals (log semiring), then

$$\min(u, v, x, y, z) - \ln(5) \le u \oplus v \oplus x \oplus y \oplus z \le \min(u, v, x, y, z)$$

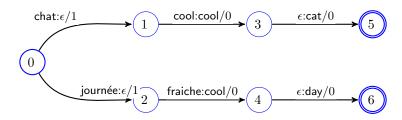

Specify the values of u, v, x, y, z that cause the lower bound to be met with equality. Specify the values of u, v, x, y, z that cause the upper bound to be met with equality.

#### Problem 5.3

Consider the problem of translating from English into French, and then back into English again. The English-to-French WFST is called E2F. With its edge weights written as surprisals (in this case,  $-\log_2 p(t)$ ), it is written as

The French-to-English WFST is called F2E. With its edge weights written as surprisals (in this case,  $-\log_2 p(t)$ ), it is written as

Find the WFST  $E2E = E2F \circ F2E$ . You do not need to show the disconnected transitions (the transitions that can't be reached from the start state).

#### Problem 5.4

Suppose you have two WFSTs,  $A = \{\Sigma_A, \Omega_A, Q_A, E_A, i_A, F_A\}$  and  $B = \{\Sigma_B, \Omega_B, Q_B, E_B, i_B, F_B\}$ . Suppose we want to create  $C = A \circ B = \{\Sigma_A, \Omega_B, Q_A \times Q_B, E_C, i_A \times i_B, F_A \times F_B\}$ , where  $Q_C = Q_A \times Q_B$  means that the states  $Q_C$  are tuples of the form  $q_C = (q_A, q_B)$ . Let the transitions be defined in the standard way,

$$\begin{split} t_A &= (p[t_A], i[t_A], o[t_A], w[t_A], n[t_A]) \\ t_B &= (p[t_B], i[t_B], o[t_B], w[t_B], n[t_B]) \\ t_C &= (p[t_C], i[t_C], o[t_C], w[t_C], n[t_C]) \end{split}$$

In each of the following cases, you're considering a pair of transitions  $t_A$  and  $t_B$ , and deciding how to create one or more transitions  $t_C$ . Specify:

## $Homework\ 5$

- the previous state,  $p[t_C]$ , as a tuple: one state from  $Q_A$ , and one from  $Q_B$  (for example, you might specify  $p[t_C] = (p[t_A], p[t_B])$ ).
- Specify  $n[t_C]$  in the same way.
- Specify also the input string  $i[t_C]$ , output string  $o[t_C]$ , and weight  $w[t_C]$ .

Specify  $(p[t_C], i[t_C], o[t_C], w[t_C], n[t_C])$  under each of the following three cases:

- (a)  $t_A$  has an  $\epsilon$  output string  $(o[t_A] = \epsilon)$ .
- (b)  $t_B$  has an  $\epsilon$  input string  $(i[t_B] = \epsilon)$ .
- (c)  $t_A$  and  $t_B$  have matching non-epsilon strings  $(i[t_B] = o[t_A] \neq \epsilon)$ .
