- Supervised learning: given pairs of data, (x_i, y_i), learn a mapping f(x) ≈ y.
- **Unsupervised learning:** given unlabeled training examples, *x_i*, learn something about them.
 - Can x_i be decomposed into signal + noise?
 - Can we group the x's into "natural classes," i.e., groups of tokens that are similar to one another?
 - Can we design a classifier that puts x_i into its natural class?

Some types of unsupervised learning

- Manifold learning: decompose x_i into signal + noise
- Clustering: group the x's into natural classes
- **Self-supervised learning:** learn a classifier that puts *x_i* into its natural class

- Signals lie on a manifold if some perturbations are impossible ("perpendicular" to the manifold)
- If signals are on a manifold, then perturbations perpendicular to the manifold are always noise, and can be ignored.

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

- The signal manifold: Each sample is
 s[n] = d[n] + ∑ a_ms[n m]. The excitation, d[n], is sparse:
 only about 10% of its samples should be nonzero.
- **The articulatory manifold:** The formant frequencies and bandwidths change slowly as a function of time, because they are shaped by positions of the tongue, jaw, and lips, and those things have mass.

PCA: Manifold = Hyperplane

If the signal is constrained to lie on a hyperplane, then the hyperplane can be found using principal components analysis (PCA).

Overview coo Manifolds coococo Clustering coococo Self-Supervision cococococo APC cococococo BERT cococococo CPC cococococo Summary coc PCA is computed by a one-layer autoencoder

A one-layer autoencoder (one matrix multiply, then a hidden layer, then the inverse of the same matrix) computes the PCA of its input.

https://commons.wikimedia.org/wiki/File:

Autoencoder_schema.png

イロト 不得 トイヨト イヨト

3

Two-layer autoencoder can compute a nonlinear manifold

- A two-layer autoencoder constrains the data, x, to lie on a nonlinear manifold of dimension = dim(z).
- The first layer nonlinearly transforms the input, then the second layer computes PCA of the result.

CC-SA 4.0.

Autoencoder_structure.png

(日) (四) (日) (日) (日)

- Speech lies on manifolds of (at least) two timescales
 - **Signal manifold:** samples are predictable from previous samples
 - Articulatory manifold: formant frequencies and bandwidths are predictable from previous formants and bandwidths

- By learning to represent the manifolds, the early layers of an ASR learn to reject irrelevant variation (noise) and keep only relevant variation (signal)
- Autoencoders explicitly learn manifolds

0000000

Summary 000

- The idea of clustering is to group the observed data into natural classes (things that sound similar).
- After grouping them into natural classes, we can then assign a label to each natural class.

Peterson and Barney, 1952. Copyright Acoustical Society of America.

Step 0: Choose random initial "means"

Step 1: Group each token with its closest mean

Step 2: Mean = average of its tokens

(日)

э

Gaussian mixture modeling is like K-means, except that each cluster has a different covariance matrix. Result can be very similar to a natural vowel space.

Fig. 1, "Building a Statistical Model of the Vowel Space for Phoneticians," (c) Matthew Aylett, 1998

In 1965, Scudder ("Probability of Error of Some Adaptive Pattern-Recognition Machines") considered the following example:

- Z_1, \ldots, Z_n, \ldots is a series of vectors.
- Each vector either contains signal + noise (Z_n = X + N_n), or just noise (Z_n = N_n).
- The signal, X, is the same every time it appears, but it is unknown.
- The noise, N_n , is zero-mean Gaussian noise with covariance matrix $K_N = \sigma^2 I$.

Unsupervised Classifier Example

Here are the questions Scudder asked:

- Suppose a classifier was asked to determine whether or not the pattern is present. What it the optimum decision rule?
- Suppose a classifier was trained without any training labels. Can it learn the optimum decision rule?

The Supervised Case

Manifolds

Overview

First, consider the supervised case. We don't know X, but we are given labels: $\theta_n = 1$ if $Z_n = X + N_n$, otherwise $\theta_n = 0$. The optimum decision rule turns out to be:

• Update the matched filter covariance estimate:

Self-Supervision

$$K_{n+1} = \left(K_n^{-1} + \theta_n K_N^{-1}\right)^{-1}$$

• Update the matched filter estimate:

Clustering

$$H_{n+1} = H_n + K_N^{-1} K_{n+1} (Z_n - H_n) \theta_n$$

• Calculate the log likelihood ratio (LLR):

$$Q_n = Z_n K_n^{-1} Z_n - (Z_n - H_n)^T (K_N + K_n)^{-1} (Z_n - H_n)$$

Threshold the LLR:

$$\hat{\theta}_n = \begin{cases} 1 & Q_n > \text{threshold} \\ 0 & Q_n \leq \text{threshold} \end{cases}$$

Overview Ivia	anifolds C	llustering	Self-Supervision	APC	BERT	CPC	Summary
	0000000 0		00000000				

In the supervised case, as

 $n
ightarrow\infty$,

- The matched filter converges $H_n \rightarrow X$.
- The matched filter covariance disappears $K_n \rightarrow 0$
- The LLR converges to a linear function of Z_n:

$$Q_n \rightarrow 2H_n^T K_N^{-1} Z_n$$
-consta

• The optimal classifier converges to a linear classifier.

Fig. 2, "Probability of Error of Some Adaptive Pattern-Recognition

Machines", (c) IEEE, 1965

Overview Manifolds Clustering Self-Supervision APC BERT CPC Summary 000 00000000 0000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 000000000 00000000 00000000

Now, consider the self-supervised case. We don't know X, and we don't know θ_n . Instead, all we have is our own classifier output, $\hat{\theta}_n$, at each time step. Can we learn the optimum classifier?

• Calculate the log likelihood ratio (LLR):

$$Q_n = Z_n K_n^{-1} Z_n - (Z_n - H_n)^T (K_N + K_n)^{-1} (Z_n - H_n)$$

• Threshold the log likelihood ratio:

$$\hat{ heta}_n = \left\{ egin{array}{cc} 1 & Q_n > {
m threshold} \ 0 & Q_n \leq {
m threshold} \end{array}
ight.$$

• Update the matched filter covariance estimate:

$$K_{n+1} = \left(K_n^{-1} + \hat{\theta}_n K_N^{-1}\right)^{-1}$$

• Update the matched filter estimate:

$$H_{n+1} = H_n + K_N^{-1} K_{n+1} (Z_n - H_n) \hat{\theta}_n$$

Figure at right shows the **supervised** case. Can we match it using a **self-supervised** learner?

- The n = 0 classifier is still a circle: any small vector is classified as $\hat{\theta}_n = 0$, any large vector is classified as $\hat{\theta}_n = 1$.
- This is a good thing! Some of the large vectors are, indeed, signals. But not all!

Fig. 2, "Probability of Error of Some Adaptive Pattern-Recognition

The self-supervised learner learns a "matched filter," H_n , such that

- The hyperplane is $H_n^T Z_n =$ threshold.
- *H_n* is the average of all of the *Z* vectors on the right side of the hyperplane.

- The classifier learns to call all big vectors "signal," and all small vectors "noise."
- It is biased: small signal vectors get misclassified as "noise."
- There is a threshold effect: if the noise covariance matrix, K_N , is too large, then the learner fails to converge.

8 Summary

Overview coco Manifolds cocococo Clustering coco Self-Supervision cococococo APC cocococo BERT cocococo CPC cocococo Summary coco The N-Gram Language Model

Claude Shannon ("A Mathematical Theory of Communication," 1948) proposed representing the probability of a sentence, $w = [w_1, \dots, w_L]$ as the product of its N-gram probabilities:

$$P(w) = \prod_{i=1}^{L} P(w_i | w_{i-1}, \dots, w_1) \approx \prod_{i=1}^{L} P(w_i | w_{i-1}, \dots, w_{i-N+1})$$

He proposed storing these probabilities in a lookup table, and using them to verify a transmitted message.

Overview coo Manifolds cooccocco Clustering cooccoccocco Self-Supervision cooccoccocco APC cooccoccocco BERT cooccoccocco CPC cooccoccocco Summary cooccoccocco The N-Gram Language Model Model

Shannon proposed that pseudo-sentences can be generated by sampling from these N-gram probability tables:

• Sentence generated by sampling from unigram (1-gram) probability tables:

REPRESENTING AND SPEEDILY IS AN GOOD APT OR COME CAN DIFFERENT NATURAL HERE HE THE A IN CAME THE TO OF TO EXPERT GRAY COME TO FURNISHES THE LINE MESSAGE HAD BE THESE.

• Sentence generated by sampling from unigram (2-gram) probability tables:

THE HEAD AND IN FRONTAL ATTACK ON AN ENGLISH WRITER THAT THE CHARACTER OF THIS POINT IS THEREFORE ANOTHER METHOD FOR THE LETTERS THAT THE TIME OF WHO EVER TOLD THE PROBLEM FOR AN UNEXPECTED.

Overview coo Manifolds cococococo Clustering coco Self-Supervision cococococo APC cococococo BERT cococococo CPC cocococo Summary coco Autoregressive Neural Language Model Verview Summary

An autoregressive neural language model expresses each word as a learned vector. The vector corresponding to word w is $x(w) = [x_1(w), \ldots, x_d(w)]$, whose elements $x_i(w)$ are learned parameters. The parameters x(w), ϕ and θ are then learned in order to minimize the cross-entropy loss:

$$\mathcal{L} = -\sum_{i=1}^{L} \ln P(w_i | w_{i-1}, \dots, w_1)$$

which is computed using an LSTM or Transformer as:

$$P(w_i|w_{i-1},\ldots,w_1) = \frac{\exp(\mathsf{Score}(w_i,h_i;\phi))}{\sum_w \exp(\mathsf{Score}(w,h_i;\phi))}$$
$$h_i = f(x(w_{i-1}),\ldots,x(w_1);\theta)$$

Overview Manifolds Clustering Self-Supervision APC BERT CPC Summary 000 00000000 0000 00000000 00000000 0000000 0000000 0000000 Autoregressive Neural Language Model

Autoregressive language modeling performance varies dramatically depending on the number of parameters of the neural net.

• GPT-2 (1.5 billion params): sometimes "In practice, he was a very conservative figure, but he was also a very conservative figure in the sense that he was a very conservative figure in the sense that he was a very conservative figure..."

• GPT-3 (175 billion params):

https://maraoz.com/2020/07/18/openai-gpt3/: "So there are lots of posts for GPT-3 to study and learn from. The forum also has many people I don't like. I expect them to be disproportionately excited by the possibility of having a new poster that appears to be intelligent and relevant. I've been following the forum for years. There are many posts I know the answers to, so I could provide a quick response and measure how well GPT-3 does with comments similar to those I make."

- In an autoregressive language model, the word representations, x(w), and the LSTM or Transformer state vectors, h_i, are summaries of the context-independent and context-dependent meaning of a word, respectively.
- Chung and Glass (2020) proposed "Autoregressive Predictive Coding" to compute similar representations for speech.

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

APC trains a transformer so that its last layer, h_L , can be used to predict the input vector n steps later:

$$h_{0} = W_{in}x + P(x)$$

$$h_{l} = \text{Transformer}(h_{l-1})$$

$$y = W_{out}h_{L}$$

$$\mathcal{L} = \sum_{i=1}^{N-n} |x_{i+n} - y_{i}|$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

- The neural net is first **pre-trained** using the autoregressive criterion on the previous page, using only the inputs (the audio).
- The system is then connected to a few extra layers of neural net, in order to perform some downstream task. Either:
 - The pre-trained network may be **frozen**, in which case only the extra layers are trained using downstream labels, or

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

- The pre-trained network is **fine-tuned** (trained in order to optimize performance on the downstream task.
- These ideas (frozen vs. fine-tuned) were laid out in BERT, so let's look at BERT.

8 Summary

Overview Manifolds Clustering Self-Supervision APC BERT CPC Summary The BERT ecosystem: Pre-training and Fine-tuning

BERT stands for Bidirectional Encoder Representations from Transformers. The idea is to pre-train an encoder, which can then be fine-tuned for downstream tasks:

Devlin et al., 2018

Overview Manifolds Clustering Self-Supervision APC BERT CPC Summary 000 00000000 0000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 000000000 000000000 000000000</td

The pre-training criterion is masked language modeling.

$$m_i = \begin{cases} 1 & \text{word } i \text{ is visible (probability: 85\%)} \\ 0 & \text{word } i \text{ is masked (probability: 15\%)} \end{cases}$$

Then, from input vectors e_1, \ldots, e_n and masked-word replacement noises v_1, \ldots, v_n , the transformer computes outputs

$$t_i = \mathsf{Transformer}\left(m_1 e_1 + (1-m_1) v_1, \dots, m_n e_n + (1-m_n) v_n
ight)$$

The loss function measures the ability of the model to predict the masked words only.

$$\mathcal{L} = -\sum_{i=1}^{n} (1 - m_i) \ln \left(\frac{\exp(\operatorname{Score}(At_i, e_i))}{\sum_{E} \exp(\operatorname{Score}(At_i, e))} \right),$$

where A is the matrix of softmax weights.

HuBERT uses the masked language modeling idea, but instead of words, it predict units such as K-means clusters of mel frequency cepstral coefficients (MFCC).

Hsu et al., 2021, Fig. 1

Overview Manifolds Clustering Self-Supervision APC BERT CPC Summary 000 00000000 0000 00000000 00000000 00000000 0000 00000000 HuBERT notation

- $X = [x_1, \dots, x_T]$ are the frames of a speech utterance, $x_t \in \Re^d$,
- $h(X) = Z = [z_1, ..., z_T]$ are the hidden units computed from X, $z_t \in \{1, ..., C\}$ where C is the number of categories.
- $M \subset \{1, \ldots, T\}$ are the frames to be masked.
- \tilde{X} is the masked sequence, i.e., masked frames are replaced by a "MASK" token.

Overview Manifolds Clustering Self-Supervision APC BERT CPC Summary 000 00000000 0000 00000000 00000000 00000000 00000000 00000000 HuBERT: Masked language modeling loss function

The loss function is

$$L(f; X, M, Z) = -\sum_{t \in M} \ln p(z_t | \tilde{X}, t),$$

where the probability is computed using a softmax:

$$p(c|\tilde{X},t) = \frac{\exp\left(\operatorname{Score}(Ao_t, e_c)\right)}{\sum_{c'=1}^{C} \exp\left(\operatorname{Score}(Ao_t, e_{c'})\right)},$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

where A is the softmax weight matrix, o_t is the transformer output, and e_c is an embedding learned for hidden unit c.

- The transformer is trained so that its outputs, *o_t*, best predict the hidden units, *z_t*.
- The hidden units are then discarded; the softmax weights A and the transformer o_t are trained to minimize

$$L_{CTC}(Y|X) + w_1L_{LM}(Y) + w_2|Y|$$

- The transformer is trained so that it accumulates information from context (*o_t*) in order to optimally predict a quantized unit.
- The quantized units are kind of like phonemes, so a Transformer that predicts them well is also good at predicting phonemes.
- The more phoneme-like the hidden units are, the more effective the pre-training works. The best procedure is:
 - Sk-means cluster the MFCC; pre-train HuBERT to predict that.
 - K-means cluster the first-round HuBERT vectors; pre-train another HuBERT.
 - K-means cluster the second-round HuBERT vectors; pre-train another HuBERT.
 - Fine tune as an ASR.

Summary

Overview coo Manifolds coocococo Clustering coococococo Self-Supervision cococococo APC cococococo BERT cococococo CPC cococococo Summary coco Contrastive Predictive Coding (CPC) CPC Summary Summary

Contrastive predictive coding was originally a form of autoregressive prediction:

Oord et al., 2018, Fig. 1

(日) (四) (日) (日) (日)

Overview Manifolds Clustering Self-Supervision APC BERT CPC Summary Obserview Occorrection Occorrection Occorrection Occorrection Occorrection Occorrection Summary The "Contrastive" in CPC CPC Occorrection Occorrection Occorrection Occorrection Occorrection

The key innovation in CPC is the loss term. A normal autoregressive language model trains c_t in order to minimize

$$\mathcal{L}_{\mathsf{ALM}} = -\sum_t \ln rac{\exp\left(\mathsf{Score}(x_{t+k}, c_t)
ight)}{\sum_{x \in V} \exp\left(\mathsf{Score}(x, c_t)
ight)},$$

where V is the entire vocabulary (all possible words). By contrast, CPC trains c_t in order to minimize

$$\mathcal{L}_{\mathsf{CPC}} = -\sum_{t} \ln \frac{\exp\left(\mathsf{Score}(x_{t+k}, c_t)\right)}{\sum_{x \in X} \exp\left(\mathsf{Score}(x, c_t)\right)}$$

where $X = \{x_1, ..., x_N\}$ is a set of N randomly chosen negative examples.

CPC can predict either continuous or discrete targets

Self-Supervision

Manifolds

- The language modeling criteria (autoregressive and MLM) require a discrete set of words. CPC, by contrast, can predict continuous vectors. The set of negative examples, X = {x₁,..., x_N}, can be either continuous-valued or discrete; the only difference is the way Score(x_{t+k}, c_t) is computed.
- The original CPC paper (Oord, 2018) used continuous vectors for speech and images, and discrete words for NLP applications.
- Wav2vec 2.0 tested both continuous and discrete speech targets, and found that discrete targets worked better, possibly because they force the transformer to learn to predict something phoneme-like.

$$\mathcal{L} = -\ln \frac{\exp\left(\mathsf{Score}(c_t, q_t)\right)}{\sum_{q \in Q_t} \exp\left(\mathsf{Score}(c_t, q_t)\right)},$$

where q_t is quantized (codebook index), but Q_t is a set of negative examples.

Overview Manifolds Clustering Self-Supervision APC BERT CPC Summary 000 00000000 0000 00000000 00000000 0000000 000 wav2vec 2.0: Other Details

Unlike HuBERT, the quantizer functions $q_t = Q(z_t)$ is learned along with the other parameters (instead of being a K-means learned offline). It's therefore necessary to prevent the trivial failure mode in which all inputs are mapped to the same codevector. To prevent this, wav2vec 2.0 adds a **diversity loss**, equal to the negative entropy of the codevector indices q_1, \ldots, q_T . If they are all the same, the entropy is zero; if they are all different, the entropy is maximized (and loss is minimized):

$$egin{aligned} \mathcal{L}_d &= -rac{1}{V} \mathcal{H}(p) = rac{1}{V} \sum_{
u=1}^V p_
u \log p_
u \ p_
u &= rac{1}{T} \sum_{t=1}^T \left(1 ext{ iff } q_t =
