Content

- What is a CSP? Why is it search? Why is it special?
- Examples: Map Task, N-Queens, Crytparithmetic, Classroom Assignment
- Formulation as a standard search
- Backtracking Search
- Heuristics to improve backtracking search
- Tree-structured CSPs
- NP-completeness of CSP in general; the SAT problem
- Local search, e.g., hill-climbing

What is search for?

 Assumptions: single agent, deterministic, fully observable, discrete environment

Search for planning

- The path to the goal is the important thing
- Paths have various costs, depths

Search for assignment

- Assign values to variables while respecting certain constraints
- The goal (complete, consistent assignment) is the important thing

Constraint satisfaction problems (CSPs)

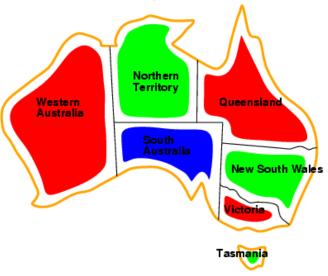

- Definition:
 - **State** is defined by variables X_i with values from domain D_i
 - Goal test is a set of constraints specifying allowable combinations of values for subsets of variables
 - Solution is a complete, consistent assignment
- How does this compare to the "generic" tree search formulation?
 - A more structured representation for states, expressed in a formal representation language
 - Allows useful general-purpose algorithms with more power than standard search algorithms

Example: Map Coloring

- Variables: WA, NT, Q, NSW, V, SA, T
- **Domains:** {red, green, blue}
- Constraints: adjacent regions must have different colors
 - Logical representation: WA ≠ NT
 - Set representation: (WA, NT) in {(red, green), (red, blue), (green, red), (green, blue), (blue, red), (blue, green)}

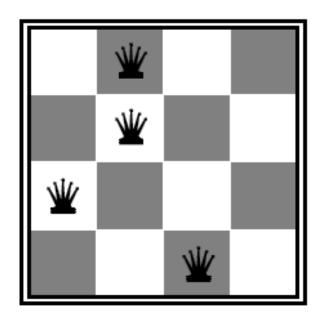

Example: Map Coloring

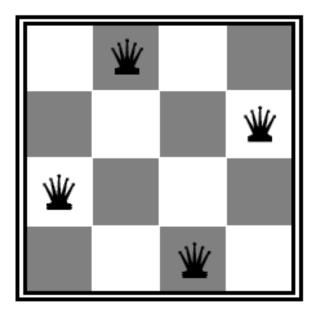

Solutions are complete and consistent assignments, e.g.,
 WA = red, NT = green, Q = red, NSW = green,
 V = red, SA = blue, T = green

Example: *n*-queens problem

• Put n queens on an $n \times n$ board with no two queens on the same row, column, or diagonal

Example: N-Queens

• Variables: X_{ii}

• **Domains:** {0, 1}

• Constraints:

| Lo | gί | C |
|----|-----------|---|
| LU | <u>8'</u> | · |

<u>Set</u>

$$\Sigma_{i,j} X_{ij} = N$$

$$X_{ij} \wedge X_{ik} = 0$$

$$(X_{ij}, X_{ik}) \in \{(0, 0), (0, 1), (1, 0)\}$$

$$X_{ij} \wedge X_{kj} = 0$$

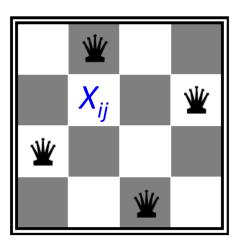

$$(X_{ij}, X_{kj}) \in \{(0, 0), (0, 1), (1, 0)\}$$

$$X_{ij} \wedge X_{i+k,j+k} = 0$$

$$X_{ij} \wedge X_{i+k,j+k} = 0$$
 $(X_{ij}, X_{i+k,j+k}) \in \{(0,0), (0,1), (1,0)\}$

$$X_{ij} \wedge X_{i+k,j-k} = 0$$

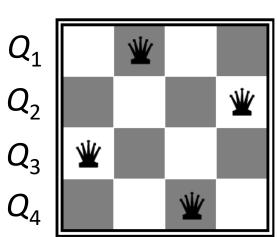

$$(X_{ij}, X_{i+k, j-k}) \in \{(0, 0), (0, 1), (1, 0)\}$$

N-Queens: Alternative formulation

- Variables: Q_i
- **Domains:** {1, ..., *N*}
- Constraints:

 $\forall i, j \text{ non-threatening } (Q_i, Q_j)$

Example: Cryptarithmetic

- Variables: T, W, O, F, U, R, X, Y
- **Domains**: {0, 1, 2, ..., 9}
- Constraints:

$$O + O = R + 10 * Y$$
 $W + W + Y = U + 10 * X$
 $T + T + X = 10 * F$
Alldiff(T, W, O, F, U, R, X, Y)
 $T \neq 0, F \neq 0, X \neq 0$

Example: Sudoku

• Variables: X_{ij}

• **Domains:** {1, 2, ..., 9}

• Constraints:

Alldiff(X_{ij} in the same *unit*)

| | | | | | 8 | | | 4 |
|---|---|---|---|-----------------|---|---|---|---|
| Н | 0 | 4 | | 1 | _ | _ | | _ |
| _ | 8 | 4 | | 1 | 6 | _ | | |
| | | | 5 | | | 1 | | |
| 1 | | 3 | 8 | | | 9 | | |
| 6 | | 8 | | X _{ij} | | 4 | | 3 |
| | | 2 | | | 9 | 5 | | 1 |
| | | 7 | | | 2 | | | |
| | | | 7 | 8 | | 2 | 6 | |
| 2 | | | 3 | | | | | |

Real-world CSPs

- Assignment problems
 - e.g., who teaches what class
- Timetable problems
 - e.g., which class is offered when and where?
- Transportation scheduling
- Factory scheduling
- More examples of CSPs: http://www.csplib.org/

Formulation as a standard search

Standard search formulation (incremental)

States:

Variables and values assigned so far

Initial state:

• The empty assignment

Action:

- Choose any unassigned variable and assign to it a value that does not violate any constraints
 - Fail if no legal assignments

Goal test:

• The current assignment is complete and satisfies all constraints

Standard search formulation (incremental)

- What is the depth of any solution (assuming n variables)?
 n (this is good)
- Given that there are m possible values for any variable, how many paths are there in the search tree?
 - $n! \cdot m^n$ (this is bad)
- All paths have the same depth, so complexity of DFS and BFS are the same (both $O\{n! \cdot m^n\}$)
- Other reasons to use DFS:
 - Maybe many possible solutions (at least n!)
 - Often, if a path fails, we can detect this early
- Today's goal: develop heuristics to reduce the branching factor

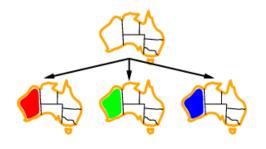

Backtracking search

Backtracking search

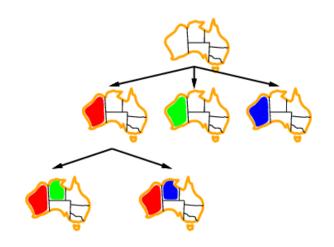

- In CSP's, variable assignments are commutative
 - For example, [WA = red then NT = green] is the same as [NT = green then WA = red]
- We only need to consider assignments to a single variable at each level (i.e., we fix the order of assignments)
 - Then there are only mⁿ leaves
- Depth-first search for CSPs with single-variable assignments is called backtracking search

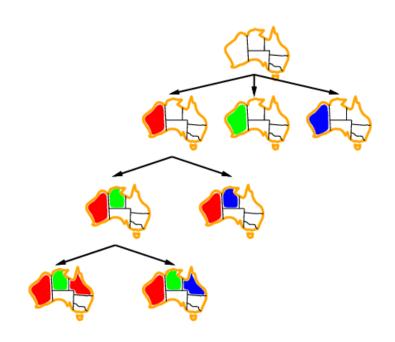

Backtracking search algorithm

```
function Recursive-Backtracking (assignment, csp)

if assignment is complete then return assignment

var \leftarrow \text{Select-Unassigned-Variable}(\text{Variables}[csp], assignment, csp)

for each value in Order-Domain-Values (var, assignment, csp)

if value is consistent with assignment given Constraints [csp]

add \{var = value\} to assignment

result \leftarrow \text{Recursive-Backtracking}(assignment, csp)

if result \neq failure then return result

remove \{var = value\} from assignment

return failure
```

- Making backtracking search efficient:
 - Which variable should be assigned next?
 - In what order should its values be tried?
 - Can we detect inevitable failure early?

Heuristics for making backtracking search more efficient

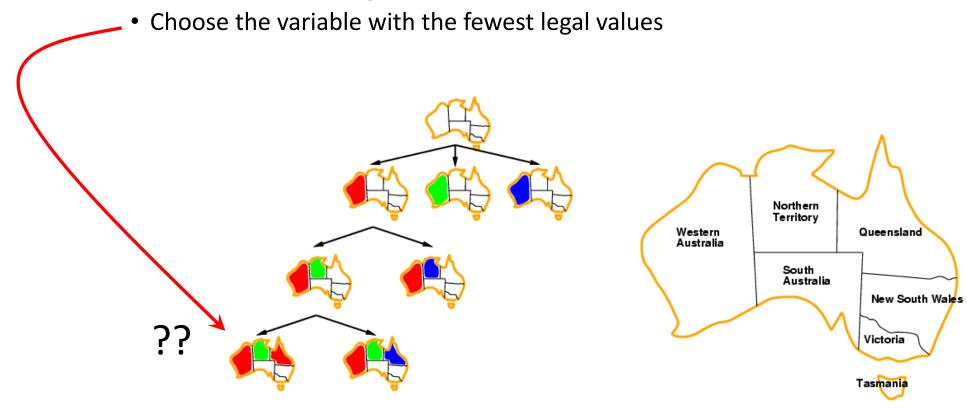

Heuristics for making backtracking search more efficient

Still DFS, but we use heuristics to decide which child to expand first. You could call it GDFS...

- Heuristics that choose the next variable to assign:
 - Minimum Remaining Values (MRV)
 - Most Constraining Variable (MCV)
- Heuristic that chooses a value for that variable:
 - Least Constraining Assignment (LCA)
- Early detection of failure:
 - Forward Checking
 - Arc Consistency

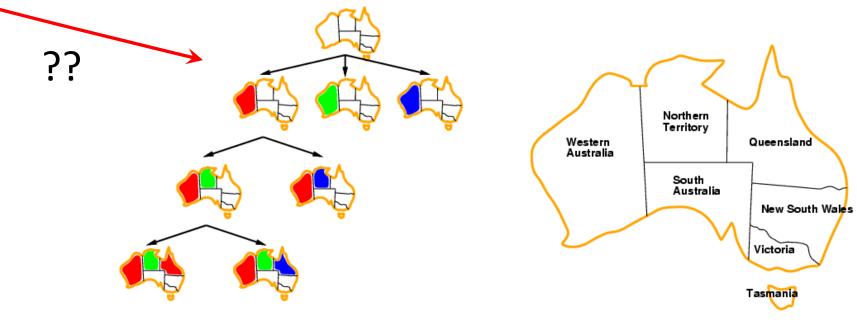

- Minimum Remaining Values (MRV) Heuristic:
 - Choose the variable with the fewest legal values

Minimum Remaining Values (MRV) Heuristic:

- Most Constraining Variable (MCV) Heuristic:
 - Choose the variable that imposes the most constraints on the remaining variables
 - Tie-breaker among variables that have equal numbers of MRV

- Most Constraining Variable (MCV) Heuristic:
 - Choose the variable that imposes the most constraints on the remaining variables
 - Tie-breaker among variables that have equal numbers of MRV

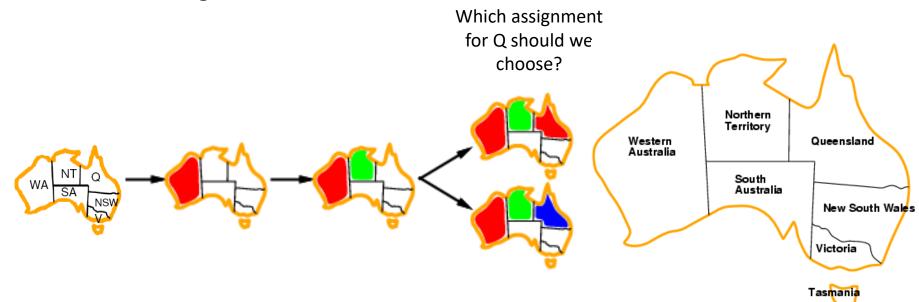

Given a variable, in which order should its values be tried?

- Least Constraining Assignment (LCA) Heurstic:
 - Try the following assignment first: to the variable you're studying, the value that rules out the fewest values in the remaining variables

Given a variable, in which order should its values be tried?

- Least Constraining Assignment (LCA) Heurstic:
 - Try the following assignment first: to the variable you're studying, the value that rules out the fewest values in the remaining variables

Early detection of failure

```
if assignment is complete then return assignment var \leftarrow \text{SELECT-UNASSIGNED-VARIABLE}(\text{VARIABLES}[csp], assignment, csp) for each value in Order-Domain-Values(var, assignment, csp) if value is consistent with assignment given Constraints[csp] add \{var = value\} to assignment result \leftarrow \text{Recursive-Backtracking}(assignment, csp) if result \neq failure then return result remove \{var = value\} from assignment return failure

Apply inference to reduce the space of possible assignments and detect failure early
```

Early detection of failure

• Forward Checking:

 Check to make sure that every variable still has at least one possible assignment

Early detection of failure

Apply *inference* to reduce the space of possible assignments and detect failure early

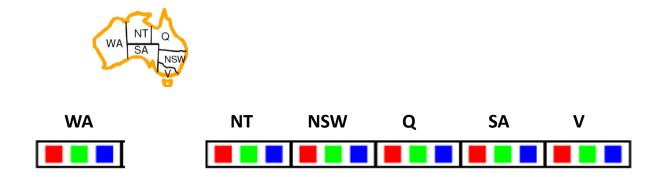

(Reminder: there are only three colors, RGB...)

Early detection of failure: Forward checking

- Keep track of remaining legal values for unassigned variables
- Terminate search when any variable has no legal values

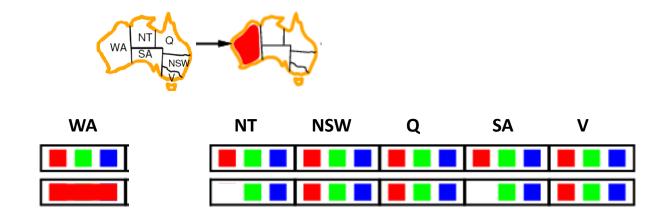

Early detection of failure: Forward checking

- Keep track of remaining legal values for unassigned variables
- Terminate search when any variable has no legal values

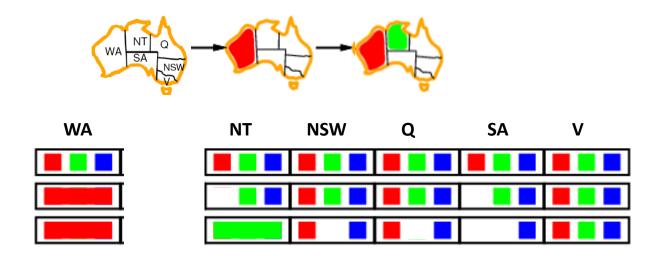

Early detection of failure: Forward checking

- Keep track of remaining legal values for unassigned variables
- Terminate search when any variable has no legal values

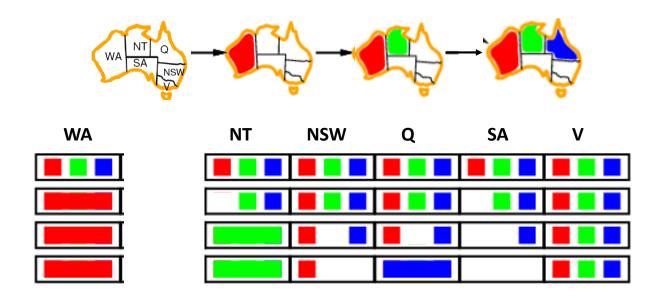

Early detection of failure: Forward checking

- Keep track of remaining legal values for unassigned variables
- Terminate search when any variable has no legal values

Early detection of failure: Forward checking

- Keep track of remaining legal values for unassigned variables
- Terminate search when any variable has no legal values

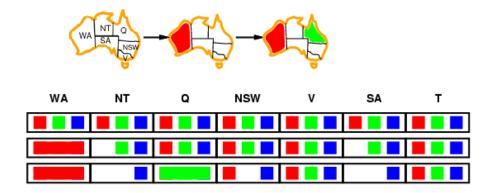

Early detection of failure

• Constraint propagation:

• Check to make sure that every PAIR of variables still has a pair-wise assignment that satisfies all constraints

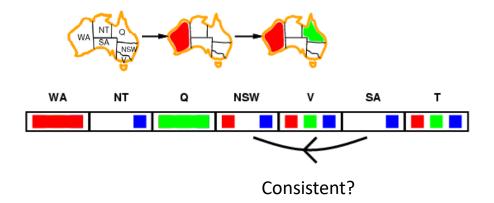

Constraint propagation

 Forward checking propagates information from assigned to unassigned variables, but doesn't provide early detection for all failures

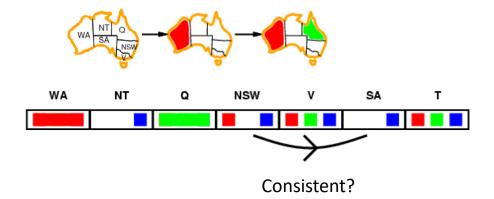

- NT and SA cannot both be blue!
- Constraint propagation repeatedly enforces constraints *locally*

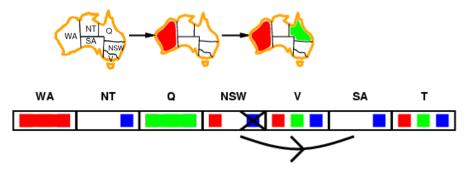

- Simplest form of propagation makes each pair of variables consistent:
 - $X \rightarrow Y$ is consistent iff for every value of X there is some allowed value of Y

- Simplest form of propagation makes each pair of variables consistent:
 - $X \rightarrow Y$ is consistent iff for every value of X there is some allowed value of Y

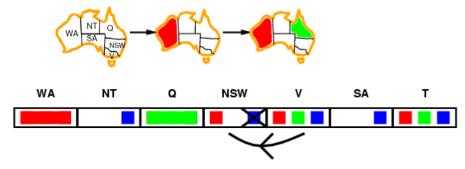

- Simplest form of propagation makes each pair of variables consistent:
 - $X \rightarrow Y$ is consistent iff for every value of X there is some allowed value of Y
 - When checking $X \rightarrow Y$, throw out any values of X for which there isn't an allowed value of Y

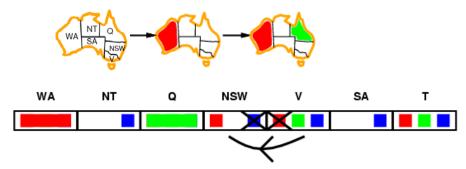

• If X loses a value, all pairs $Z \rightarrow X$ need to be rechecked

- Simplest form of propagation makes each pair of variables consistent:
 - $X \rightarrow Y$ is consistent iff for every value of X there is some allowed value of Y
 - When checking $X \rightarrow Y$, throw out any values of X for which there isn't an allowed value of Y

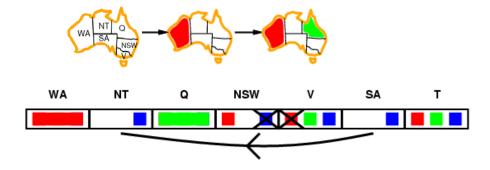

• If X loses a value, all pairs $Z \rightarrow X$ need to be rechecked

- Simplest form of propagation makes each pair of variables consistent:
 - $X \rightarrow Y$ is consistent iff for every value of X there is some allowed value of Y
 - When checking $X \rightarrow Y$, throw out any values of X for which there isn't an allowed value of Y

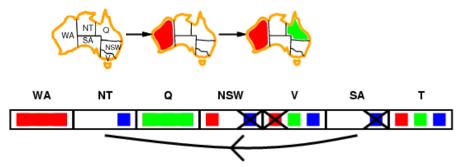

• If X loses a value, all pairs $Z \rightarrow X$ need to be rechecked

- Simplest form of propagation makes each pair of variables consistent:
 - $X \rightarrow Y$ is consistent iff for every value of X there is some allowed value of Y
 - When checking $X \rightarrow Y$, throw out any values of X for which there isn't an allowed value of Y

- Simplest form of propagation makes each pair of variables
 consistent:
 - $X \rightarrow Y$ is consistent iff for every value of X there is some allowed value of Y
 - When checking $X \rightarrow Y$, throw out any values of X for which there isn't an allowed value of Y

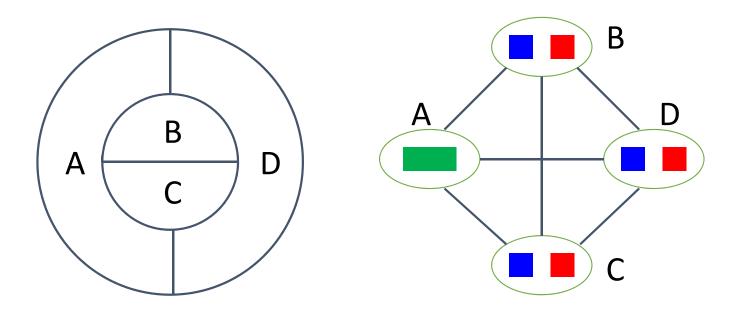

- Arc consistency detects failure earlier than forward checking
- Can be run before or after each assignment

Arc consistency algorithm AC-3

```
function AC-3( csp) returns the CSP, possibly with reduced domains inputs: csp, a binary CSP with variables \{X_1, X_2, \ldots, X_n\} local variables: queue, a queue of arcs, initially all the arcs in csp while queue is not empty (X_i, X_j) \leftarrow \text{Remove-First}(queue) if Remove-Inconsistent-Values(X_i, X_j) then for each X_k in Neighbors[X_i] do add (X_k, X_i) to queue
```

```
function Remove-Inconsistent-Values (X_i, X_j) returns true iff succeeds removed \leftarrow false for each x in Domain [X_i] if no value y in Domain [X_j] allows (x,y) to satisfy the constraint X_i \leftrightarrow X_j then delete x from Domain [X_i]; removed \leftarrow true return removed
```

Does arc consistency always detect the lack of a solution?

 There exist stronger notions of consistency (path consistency, k-consistency), but we won't worry about them

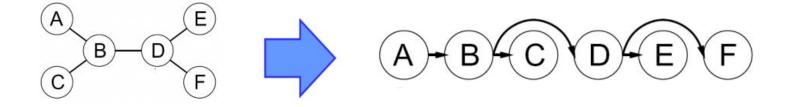

Tree-structured CSPs

Tree-structured CSPs

- Certain kinds of CSPs can be solved without resorting to backtracking search!
- Tree-structured CSP: constraint graph does not have any loops

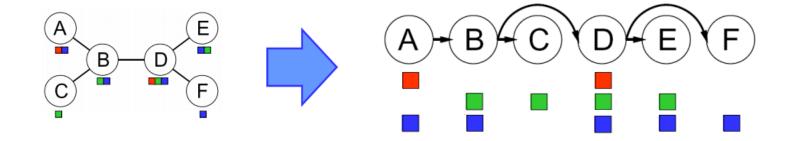

• Choose one variable as root, order variables from root to leaves such that every node's parent precedes it in the ordering

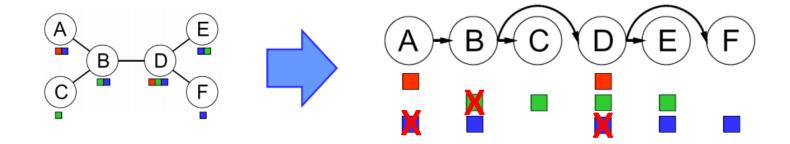

http://cs188ai.wikia.com/wiki/Tree Structure CSPs

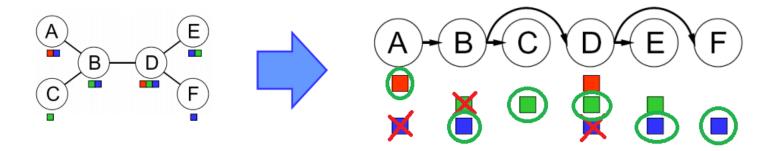

- Choose one variable as root, order variables from root to leaves such that every node's parent precedes it in the ordering
- Create a graph listing all of the values that can be assigned to each variable.

- Choose one variable as root, order variables from root to leaves such that every node's parent precedes it in the ordering
- Create a graph listing all of the values that can be assigned to each variable.
- BACKWARD ARC CONSISTENCY: check arc consistency starting from the rightmost node and going backwards

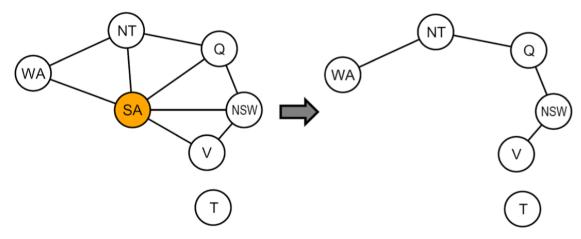

- Choose one variable as root, order variables from root to leaves such that every node's parent precedes it in the ordering
- Create a graph listing all of the values that can be assigned to each variable.
- BACKWARD ARC CONSISTENCY: check arc consistency starting from the rightmost node and going backwards
- FORWARD ASSIGNMENT PHASE: select an element from the domain of each variable going left to right. We are guaranteed that there will be a valid assignment because each arc is consistent

- If n is the number of variables and m is the domain size, what is the running time of this algorithm?
 - O(nm²): we have to check arc consistency once for every node in the graph (every node has one parent), which involves looking at pairs of domain values

Nearly tree-structured CSPs

- Cutset conditioning: find a subset of variables whose removal makes the graph a tree, instantiate that set in all possible ways, prune the domains of the remaining variables and try to solve the resulting tree-structured CSP
- Cutset size c gives runtime $O(m^c (n-c)m^2)$

NP-Completeness and the SAT Problem

- Running time is $O(nm^2)$ (n is the number of variables, m is the domain size)
 - We have to check arc consistency once for every node in the graph (every node has one parent), which involves looking at pairs of domain values
- What about backtracking search for general CSPs?
 - Worst case $O(m^n)$
- Can we do better?

Computational complexity of CSPs

- The satisfiability (SAT) problem:
 - Given a Boolean formula, is there an assignment of the variables that makes it evaluate to true?

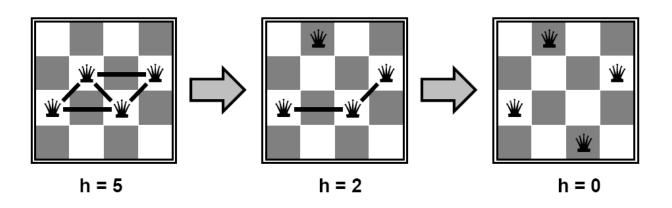

$$(X_1 \vee \overline{X}_7 \vee X_{13}) \wedge (\overline{X}_2 \vee X_{12} \vee X_{25}) \wedge \dots$$

- SAT is *NP-complete*
 - NP: a class of decision problems for which
 - the "yes" answer can be verified in polynomial time
 - no known algorithm can find a "yes" answer, from scratch, in polynomial time
 - An NP-complete problem is in NP and every other problem in NP can be efficiently reduced to it (Cook, 1971)
 - Other NP-complete problems: graph coloring, n-puzzle, generalized sudoku
 - <u>It is not known whether P = NP</u>, i.e., no efficient algorithms for solving SAT in general are known

Local search, e.g., hill climbing

Local search for CSPs

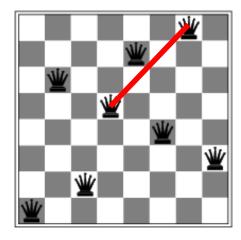

- Start with "complete" states, i.e., all variables assigned
- Allow states with unsatisfied constraints
- Attempt to improve states by reassigning variable values
- Hill-climbing search:
 - In each iteration, randomly select any conflicted variable and choose value that violates the fewest constraints
 - I.e., attempt to greedily minimize total number of violated constraints

h = number of conflicts

Local search for CSPs

- Start with "complete" states, i.e., all variables assigned
- Allow states with unsatisfied constraints
- Attempt to improve states by reassigning variable values
- Hill-climbing search:
 - In each iteration, randomly select any conflicted variable and choose value that violates the fewest constraints
 - I.e., attempt to greedily minimize total number of violated constraints
 - Problem: local minima

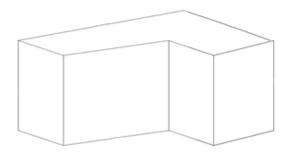

h = 1

Applications that look a lot like intelligence...

CSP in computer vision: Line drawing interpretation

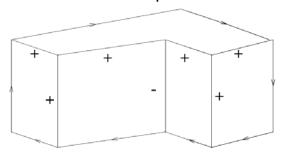

An example polyhedron:

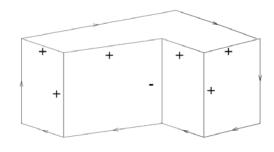

Variables: edges

Domains: $+, -, \rightarrow, \leftarrow$

Desired output:

CSP in computer vision: Line drawing interpretation

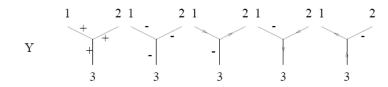

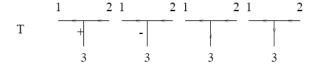

Four vertex types:

Constraints imposed by each vertex type:

CSP in computer vision: 4D Cities

- 1. When was each photograph taken?
- 2. When did each building first appear?
- 3. When was each building removed?

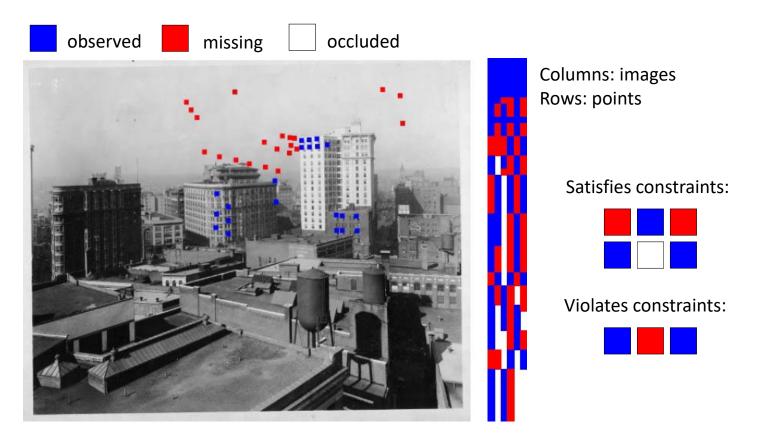

Set of Photographs:

G. Schindler, F. Dellaert, and S.B. Kang, <u>Inferring Temporal Order of Images From 3D Structure</u>, IEEE Computer Society Conference on Computer Vision and Pattern Recognition (CVPR), 2007.

http://www.cc.gatech.edu/~phlosoft/

CSP in computer vision: 4D Cities

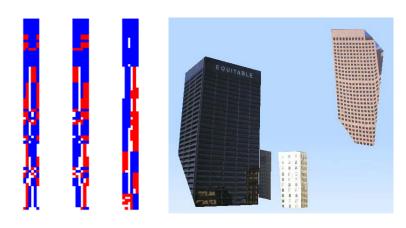

• Goal: reorder images (columns) to have as few violations as possible

CSP in computer vision: 4D Cities

- Goal: reorder images (columns) to have as few violations as possible
- Local search: start with random ordering of columns, swap columns or groups of columns to reduce the number of conflicts

 Can also reorder the rows to group together points that appear and disappear at the same time – that gives you buildings

Summary

- CSPs are a special kind of search problem:
 - States defined by values of a fixed set of variables
 - Goal test defined by constraints on variable values
- **Backtracking** = depth-first search where successor states are generated by considering assignments to a single variable
 - Variable ordering and value selection heuristics can help significantly
 - Forward checking prevents assignments that guarantee later failure
 - Constraint propagation (e.g., arc consistency) does additional work to constrain values and detect inconsistencies
- Complexity of CSPs
 - NP-complete in general (exponential worst-case running time)
 - Efficient solutions possible for special cases (e.g., tree-structured CSPs)
- Alternatives to backtracking search: local search
